THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXV.

FROM MAY 9 TO OCTOBER 31, 1890.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1890.

INDEX TO "THE ELECTRICIAN."

VOL. XXV.

General Alphabetical Index.

Italic figures denote that the subject matter is in the "Leading Articles" or in the "Editorial Notes."

A

ABEL, SIR FREDERICK.
Presidential Address (British Association), 495.
Accidents, 247, 571, 601, 625.
Accumulators at the Berlin Telegraph Office, 221.
Accumulators, Charging of, by Alternating Currents, 80.
Accumulators Left on Open Circuit, Discharge of: by Gaston Roux, 754.
Accumulator Plates, Italian Duty on, 108.
Accumulators with Porous Partitions, 220, 265.
Accumulators, Seizures, of, in France, 54.
Accumulator Tramcars, 43, 359, 396, 425, 470.
Accumulators of Various Makers, Tests of, 434, 539.
Accumulators (*see also* Batteries, Storage).
Accumeter, Electric, 56.
Aerial Conduit, Method of conveying Electric Wires, 4.
Aerial Navigation, The Renard Battery and, 55.
Agriculture, Application of Electricity to, *26*; by N. Specnew, 31.
Air Condensers of the British Association: by R. T. Glazebrook, 616, 637.
Alcohol, Electrical "Ageing of," 56.
All-Copper Rail Bonds, 451.
Alloy, A New, 451.
Alloys, Ferro-Manganese-Copper, Resistance of, 452.
Alloys for Fuses, 667.
Alternate Currents in Parallel Conductors of Homogeneous or Heterogeneous Substance: by Sir William Thomson, 510.
Alternate Currents, Measurement of the Repulsive Force exerted by, *26*.
Alternating-Current Apparatus, Some Experiments upon: by Harris J. Ryan, 312.
Alternating-Current Motor, 5, 388, 451.
Alternating *versus* Continuous Currents in relation to the Human Body, 44; by A. E. Kennelly, 173; by H. M. Sayers, 18; by J. Swinburne, 581; by H. Newman Lawrence and Arthur Harries, M.D., 640.
Alternator, A Suggested, 404.
Aluminium, Electro-Deposition of, *367*.
American Association for the Advancement of Science, 470, 528.
American and English Electric Lighting Accessories, Notes on the Differences between, *363*; by F. Bathurst, 376.
American Electrical Units, 633.
American Institute of Electrical Engineers, Meeting of, 100, *107*, 120, 186.
American Invention, An, 571.
American Telegraphers' Fast-Sending Tournament: by Patrick B. Delany, 71.
Ammeters and Voltmeters, Standard Optical, Best Dimensions for, *607*; by A. E. Kennelly, 701.
Anderson, Sir James, Dinner to, 109, 140.
Anglo-French Submarine Cables, 370.
Anglo-Scandinavian Cables, New, 165.
Animal Tissues, Electrolysis of, 509.
Annual Dinners, 304, 337, 417, 600.
Anti-Effective Copper in Parallel Conductors or in Coiled Conductors for Alternate Currents: by Sir William Thomson, 512.
Arc Lamp Competition, 130.
Arc Lamp Tablets, Wade's Patent, 418.

Arc Lamps—
Doubrava, 356.
Zweifel, 466.

Arc Light Formula, 81.
Arc Lights Insects and, 453.
Army Manœuvres, French, The Telephone in the, 549.
Artistic Electric Light Fittings, 531.
Artistic Electric Lighting, 139.
Asbestos Fireproof Curtains, 502.
Association of American Railway Telegraph Superintendents, 238.
Association of Edison Illuminating Companies, 571.
Atmospheric Electricity, Earthquakes and, 108
Atmospheric Electricity, Observations on, 165, 478.
Attack on a Cable Station, 275.
Australasian Cable Rates, *53*, *79*, *137*, 140, 156, 165, 212, *267*.
Australia and New Zealand, Duplicate Cable between, 2.
Australia, Duplication of Telegraphic Communication with, 109.
Australian Cables, Interruption of the, 274, 303.
Australian Postmasters-General, Conference of, 27.
Australian Transcontinental Telegraph Line, 165.
AYRTON, W. E., LAMB, C. G., SMITH, E. W., and WOODS, M. W.
Working Efficiency of Secondary Cells, 283, 319, 342, 382, 412.

B

Ballistic Electrometer, 201.
Balloon, Meudon Dirigible, 246.
BARBER-STARKEY, W. J. S.
Secondary Cells, 719.
BARKER, E. RAYMOND.
Suspended Coil in Cable Work, 672.
Barmer, Electric Railway at, 347.
BARRETT, J. P.
Electrical Industries and the World's Fair, 497.
Bath, The Charge for Electricity at, *336*.
BATHURST, F.
Notes on the Difference between the English and American Electric Lighting Accessories, 376.

Batteries (Primary)—
Cabanyes, 108.
Gassner Dry, 508.
Germain Dry, 155.
Henderson, for Surgeons, 214.
Kousmine Diffusion, 167.
Scharf Gas, 4.
Silvertown Dry, 4.

Batteries (Storage) (*see also* Accumulators)—
E. P. S. at the Chelsea Electricity Supply Company's Station, 146.
Johnson, 659.
Laurent-Cely, 82, 108.
Reynier, New, 186.
Schoop Gelatinous, *245*, 253.
Series, 248.
Standard, 239.
Tudor, 193.
Weymersch, *192*.

Battery Plates, Carbon, Improved Connection for, 220.
Baxter Motor, 721.
Belgian Lighting Statistics, 29.
Belgium and Germany, Telephone Line between, 193.
BELL, DR. LOUIS.
Inductive and Earth Interference with Telephone Service, 620.
Bell, Electric Combination, Portable, 35.
Belts, Leather and Canvas-Rubber, Comparative Tests of: by Samuel Webber, 714.
Belts, Sparks from, 611.
Ben Nevis, The Telephone on, 397.
BENNETT, A. R.
Observations on Currents originating in ordinary Aerial Telegraph Conductors, 309.
Protection of Buildings from Lightning, 684.
Berlin Telegraph Office, Accumulators at the, 221.
Bermudas and Halifax, Cable between the, 55, *79*, 164, 218, 273, 729.
Berthoud-Borel Cables, 164.
Bicycles for Telegraph Messengers, 81, 187.
Bi-metallic Wire, Martin, 451, 600.
Birmingham Church, The Telephone in a, 571.
Birmingham Exhibition, 82.
Birmingham, Opening of an Electric Tramway at, 323.
BLAKESLEY, T. H.
Determination of the Work Done upon the Cores of Iron in Electrical Apparatus subject to Alternating Currents, 746.
Blower, Electric, 102.
Board of Trade, Policy of the, *62*.
Board of Trade, Provisional Orders granted by the, 110, 194, 371, 444, 559.
Board of Trade Railway Rates Inquiry, 15, 27, 43, 72, 356, 477.
Board of Trade Rules, New, 425, *460*, 466, 667.
Board of Trade and Electric Lighting Companies, *1*, 4, 13.
Boiler Experiments by the Manchester Steam Users' Association, 600.
Boilers, Sectional and Lancashire, *296*.
BOLTZMANN, L.
Experiments of Hertz, 469.
Boston (U.S.) Elevated Railway, 103.
BOURNE, W. F.
Testing Iron, 618.
BOUTY, M. E.
Residual Charge of Condensers, 415.
Boy Messengers, Electric Call System for, 133, 274.
BOYS, C. V., BRISCOE, A. E., and WATSON, W.
Measurement of Electro-Magnetic Radiation, 210.
Brass, Magnetic, *507*, *538*, 565.
Bremen Exhibition, 426.
Brewers' Exhibition, 722.
BRISCOE, A. E., BOYS, C. V., and WATSON, W.
Measurement of Electro-Magnetic Radiation, 210.
Bristol University College, 273, 453.
British Association, Meeting of, at Leeds, 140, *423*, *444*, *475*, 495, *505*, *507*, *518*, 519, 520, 573.
British Museum, Evening Visitors to the, 303.
Brooklyn Navy Yard, Electricity in, 416.
Burmah, The Telegraph in, 108.

C

Cabanyes Primary Battery, 108.
Cable Accident, Remarkable, *337*, 338.
Cable Extensions in East Africa, 451, 477, 506.
Cable Ship Gear, Improvements in: by H. D. Wilkinson, 190.
Cable Ships, Picking-up Machines for, 353.
Cable Traction *v.* Electric Traction, 699.
Cables, Concentric, Siemens and Halske, 351.
Calculating Disc, Cuttriss, 109.
Cambridge University, Engineering at, 699.
Canada, Electric Traction in, 668.
Canada-Florida Cable, Proposed, 539.
Canadian Fire Insurance Companies and the Electric Light, 700.
Cape of Good Hope Telegraphs, 249.
Cape Town Cable Station, The: by H. D. Wilkinson, 223.
Carbon Battery Plates, Improved Connection for, 220.
Carbon Brush Patent, *79*.
Carbons, Arc-Light, Life and Efficiency of: by Louis B. Marks, 150, 177.
CARDEW, MAJOR P.
Treatment, Regulation, and Control of Electric Supply by the Legislature and the Board of Trade, 116, 154, 182.
Cardiff University College, 81.
Carnot's Principle, Diamagnetism tested by, 371.
Carré, M., Award to, 451.
CARTER, E. T.
Magnetic Circuit, The, 231.
Cataphoric Medication, 428, 472, 699.
Ceiling Rose, White's Patent Divided Wire, and Pulley Attachment, 75.
Celluloid, The Manufacture of, 248.

Central Lighting Stations—
Aviles, 303.
Bath, 204.
Bradford, 426, 731.
Chelsea, 84, 146, 347, 417.
Collias, near Nimes, 507.
Deptford, 699, 729.
Copenhagen, 626.
Dresden, 304, 539.
Gothenburg, 444.
Hamburg, 729.
Hastings and St. Leonards, 336.
Italian, List of, 409.
Kensington Court, 381.
Keswick, 56, 219, 698.
Konigsberg, 55, 700.
Leghorn, 369.
Locle (Switzerland), 304.
Metropolitan Electric Supply Company's, *697*, 703, 737.
Milan, 408.
Paris, 219.
Reichenhall (Bavaria), 508.
Rome, 315.
St. Austell, 139.
St. Moritzbad, 273, 370.
Sardinia Street, 703, 737.
Tivoli, 303.
Troyes, 192.
Valencia, 192.
Westinghouse at East Liberty (Pa.), 710.
Westminster Electric Supply Company's, 741.

Central London Railway, 1, 14, 29, *137*, 138, 157, 164, 211, 227, 263, *272*, 283.
Central Station Companion, 417.
Central Station Struck by Lightning, 274.
Central Stations of the Metropolitan Electric Supply Company: by Dr. J. A. Fleming, 703, 737.
Chamberlain's Composite "Wave" Pinion for Electric Cars, 283.
Champion Cut-out, 659.
Change-over Switch at Rome, 352.
Channel Telephone Cable, 342, *450*, 637.
Charlesworth Projector Plant, 185.
Charterhouse Science and Art Schools and Literary Institute, 539.
Charts, Magnetic, 601.
Chelsea Electricity Supply Company's Station and Sub-Stations, 84, 146, 347, 417.
Chemical Research, A New Method and Department of, *475*; by Dr. G. Gore, 490.
Chicago Telegraph Office, Dynamo Plant at the, 221.
Chicago Telephone Exchange, The Storage Battery in the, 572.
China and Tonquin Telegraph, 54.
China, Telegraphs in, 397, 607.
Chinese Telephone, A, 540.
Chin-Lushai, The Telegraph Department at, 571.
Chronograph, Electric, *80*.
CHRYSTAL, G.
Verification of Ohm's Law, 309.
City and Guilds of London Institute, 247, 304, 478, 571, 668, 699, 731.
City and South London Railway, 2, 166, 218, *727*, 730.
City Notes, &c., 23, 51, 77, 105, 135, 161, 189, 215, 243, 269, 299, 333, 365, 393, 421, 447, 473, 503, 535, 567, 597, 629, 663, 695, 725, 757.
Civil and Mechanical Engineers' Society, 80.
CLASSEN, H.
Easy Method of Producing the Active Spark in Hertz's Experiments, 469.
Clerk-Maxwell Scholarship, 80.
Clermont-Ferrand Electric Railway, 81.
Climate, A Fine, 337.
Clocks, Electric, 252.
Coal-cutting Machinery, 397, 398.
Coal Mines, Electric Traction in, 2, 275.
Coal, Waste, Utilisation of, 371.
Coast Defence, Search Lights and, 539.
Coefficient of Friction, Effect of Electricity on the, 306
Coefficient of Mutual Induction of Two Parallel Wires: by Dr. Cary T. Hutchinson, 746.
Coffin Method of Electric Welding, *476*.
Cohen Smoke-Consuming Furnace, 130.
Coils, Resistance, Values of Certain Standard: by R. T. Glazebrook, 613.
Collieries, The Electric Light in, 729.

Commercial and Industrial Finance, 269.
Commune, Telegraphy during the, 478.

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, &c.

(Abbreviations:—Div., Dividend; Mtg., Meetings of Shareholders; Rev., Revenue; Rpt., Reports of Directors.)

African Direct Telegraph Company—215.
Allgemeine Electricitäts Gesellschaft—269.
Aluminium Company—Mtg., 535.
Aluminium Industrie Gesellschaft of Neuhausen—Div., 135.
Anglo-American Telegraph Company—Div., 629; Rpt., 331; Mtg., 390.
Anglo-Portuguese Telephone Co.—215; Mtg., 510.
Bankers' and Merchants' Telegraph Company of New York—503.
Beale's—215.
Bell Telephone Company—Div., 161, 535.
Bell's Asbestos Company—663; Div., 333.
Berliner Electricitäts-Werke—Div., 629.
Birmingham Tramway Company—Mtg., 421.
Brazilian Submarine Telegraph Company—Rev., 51, 77, 105, 161, 189, 215, 243, 269, 333, 365, 393, 421, 447, 473, 503, 535, 567, 597, 629, 695, 725, 757; Div., 135, 663; Rpt., 695; Mtg., 19, 725.
Bright Platinum Plating Company—365.
Brush Electrical Engineering Company—Rpt., 502; Mtg., 532.
Chili Telephone Company—Rpt., 364; Mtg., 419.
City and South London Railway Company—Rpt., 393; Mtg., 420.
Column Printing Telegraph Company—161, 215.
Commercial Cable Company—77; Div., 135, 243, 269; Rev., 535.
Compagnie Nationale d'Electricité—503.
Consolidated Telephone Construction and Maintenance Company—77; Mtg., 103; Div., 725.
Crompton and Co.—Rpt., 298; Mtg., 331.
Cuba Submarine Telegraph Company—Rev., 23, 135, 243, 393, 503, 663; Div., 333; Rpt., 364; Mtg., 391.
Dellagana (B.) and Co.—Div., 629.
Dick, Kerr and Co.—135.
Direct Spanish Telegraph Company—Rev., 23, 135, 269, 393, 503, 663; Div., 567; Rpt., 597; Mtg., 627, 695.
Direct United States Cable Company—Rev., 695, 725; Div., 299; Rpt., 297; Mtg., 360, 725.
Eastern and South African Telegraph Company—189, 333.
Eastern Extension, Australasia, and China Telegraph Company—333; Rev., 23, 135, 269, 393, 503, 663; Rpt., 694; Div., 243, 597; Mtg., 722.
Eastern Telegraph Company—333; Div., 243, 597, 629; Rev., 23, 135, 269, 393, 503, 663; Rpt., 267; Mtg., 294, 327.
Edison and Swan United Electric Light Company—Div., 299; Rpt., 332; Mtg., 362.
Electrical Engineering Company of Ireland—Mtg., 241.
Electric and General Investment Company—77.
Electric Construction Corporation—421, 473.
Elmore's Austro-Hungarian Patent Copper Depositing Company—629.

COMPANIES' MEETINGS, &c. (*continued*).

Elmore's French Patent Copper Depositing Company—535, 757.
Elmore's Patent Copper Depositing Company—365, 473, 503, 597; Div., 333; Mtg., 363.
Elmore's Wire Manufacturing Company—421, 597, 757; Mtg., 297.
Exchange Telegraph Company—161.
Exeter Electric Light Company—23; Rpt., 330.
Ferrotype Automatic Photograph Company—77.
Fox (Edwin) and Co.—365.
General Electric Company—Mtg., 447.
General Electric Power and Traction Company—105; Mtg., 596.
Grange Syndicate—421.
Great Northern Telegraph Company—Div., 189; Rev., 23, 135, 269, 393, 503, 663.
Greenwood and Batley—Mtg., 135.
Globe Telegraph and Trust Company—Div., 299, 597; Rpt., 332; Mtg., 361.
Halifax and Bermudas Cable Company, 243, 333, 447.
Hastings and St. Leonards-on-Sea Electric Light Company—Mtg., 104.
Helios Company—189.
Hornsby and Sons—Div., 77.
House-to-House Electric Light Supply Company—Mtg., 21.
India Rubber Estates Company—269.
India Rubber, Gutta Percha and Telegraph Works Co.—Mtg., 267.
Indo-European Telegraph Company—Div., 757.
International Cable Company—365.
International Okonite Company—243, 597; Mtg., 661.
Italian Edison Company,—54.
Keswick Electric Light Company—Mtg., 393.
Laing, Wharton and Down Construction Syndicate—Div., 215.
Leon Cobalt and Copper Mining Company—51.
Liverpool Overhead Railway Company—Mtg., 421.
Manchester Edison-Swan Company—Mtg., 363.
Manganese Brass and Bronze Company—Div., 333.
Manitoba Electric and Gas Light Company—215.
Maxim Weston Electric Company—Rpt., 22; Mtg., 49, 243, 391.
M'Lellan, P. and W.—Div., 333.
Montevidean and Brazilian Telegraph Company—269.
Montevideo Telephone Company—Rpt., 757.
Morgan Crucible Company—269.
Muntz's Metal Company—Div., 535.
Mutual Telephone Company—23; Mtg., 365.
Namaqua Copper Company—Mtg., 105.
National Association for the Exemption of Machinery from Rating—Mtg., 421.
National Telephone Company—447, 535; Rpt., 242; Mtg., 295.
North Metropolitan Tramways Company—Mtg., 393.
Norwich Electricity Company—Mtg., 135.
Notting Hill Electric Lighting Company—135, 393.
Panulcillo Copper Company—Mtg., 77.
Phœnix Electric Light and Power Company—135.
Pilsen, Joel, and General Electric Light Company—535.
Poole and White—Mtg., 189.
Reuter's Telegram Company—Div., 663.
Sheffield Telephone Exchange and Electric Light Company—Mtg., 421.
Société Générale des Téléphones—Div., 161.
Southend Tramway—Rev., 421.
South of England Telephone Company—Div., 757; Mtg., 329.
Spanish National Submarine Telegraph Company—105.
Submarine Cables Trust—Mtg., 20, 629.
Telephone Company of Austria—215; Div., 663; Rpt., 332; Mtg., 362.
Telephone Construction and Maintenance Company—269; Mtg., 295.
Trustees, Executors, and Securities Insurance Corporation—503.
United Electric Light and Power Company—567.
United River Plate Telephone Company—51, 105, 161; Rpt., 298.
Universal Automatic Machines Company—Mtg., 333.
Venezuela Telephone and Electrical Appliances Company—23, 243; Mtg., 333.
Wendigo Copper Company—333.
West African Telegraph Company—Div., 189; Mtg., 215, 240.
West Coast of America Telegraph Company—Rev., 23, 135, 243, 663; Div., 365, 393, 503; Rpt., 22; Mtg., 48.
West End Street Railway Company of Boston—Div., 269.
Western and Brazilian Telegraph Company—23; Rev., 51, 77, 105, 135, 161, 189, 215, 243, 269, 299, 333, 365, 393, 421, 447, 473, 503, 535, 567, 597, 663, 725, 757; Mtg., 46
Western Counties and South Wales Telephone Company—Mtg., 133, 243; Div., 393.
Western Union Telegraph Company—135; Rev., 629. Div., 161, 535; Rpt., 757.
West India and Panama Telegraph Company—Rev., 23, 105, 135, 189, 243, 333, 393, 447, 503, 567, 597, 663, 725; Div., 725; Mtg., 19.
Westinghouse Electric Company—189; Mtg., 365.
Winfield's—Rpt., 503; Mtg., 567.
Woodhouse and Rawson United—23, 189, 597; Rpt., 661; Mtg., 660, 663, 692.
Wrexham and District Electric Supply Company—Mtg., 51.

COMPANIES (NEW) REGISTERED.

The following Companies have been Registered under the Limited Liability Acts.

Allen, Everitt and Sons, 189.
Amalgamated Electricity Supply Company, 333.
Atlas Engine Company, 447.
Barry and Cardiff Electric Light and Power Supply Company, 268.

COMPANIES (NEW) REGISTERED (*continued*)

Baxter s, 242.
Beale's, 242.
Bishops Stortford Electric Light and Steam Laundry Company, 135.
Blackman Ventilating Company, 298.
Blake and Knowles' Steam Pump Works, 299.
Bristol Electricity Supply Company, 268.
British Gas Lighting Improvement Company, 394.
British Insulated Wire Company, 757.
Bullers, 695.
Camberwell and Islington Electric Light and Power Company, 268.
Canterbury Electricity Supply Company, 268.
Cardiff Electricity Supply Company, 268.
Ceres Ironworks, 473.
Column Printing Telegraph Company, 189.
Combination Telephone and Electrical Engineering Company, 629.
Dashwood and Sons, Arthur, 242.
Devonshire Electric Light and Power Supply Company, 268.
Dick, Kerr and Co., 189.
District Messenger Service and News Company, 268.
Earthy Metals Company, 365.
East Coast Electric Light and Power Supply Company, 268.
Edinburgh Electric Supply Corporation, 242.
Electrical Inventions Company, 597.
Electricity Supply Companies Union, 333.
Electric Welding Company, 23.
Electro-Chemical Syndicate, 757.
Electro Metallurgical Company, 663.
Elmore's Austro-Hungarian Patent Copper Depositing Company, 629.
Elmore's French Patent Copper Depositing Company, 663.
Engineer, The, 135.
Ferranti, S. Z. de, 268.
Franco-African Lighting Syndicate, 365.
Freedman Battery Company, 535.
General Electric Power and Traction Company, 105.
Glasgow and District Pulsion Telephone Company, 567.
Gordon Electric Traction Syndicate, 447.
Gordon, J. E. H. and Co., 629.
Grangemouth Gas Company, 299.
Hanley (Staffordshire) Electricity Supply Company, 262.
Head, Wrightson and Co., 243.
India Rubber Estates' Company, 268.
International Okonite Company, 243.
Ipswich Electricity Supply Company, 268.
Kaye and Sons (Joseph), 268.
Kent Patent Arc Lamp Company, 189.
Kidderminster Electric Light and Power Supply Company, 268.
Lamp Manufacturing Company, 503.
Lartigue Railway Construction Company, 503.
Lawes (John Bennet) and Co., 299.
Leeds and London Electrical Engineering Company, 663.
Loughboro' Electricity Supply Company, 268.
Manchester Electricity Supply Company, 268.
Mill's Patent Sectional Boiler Company, 503.
Mulholland, Maugham and Company, 393.
Muntz's Metal Company, 243.
New Cadogan and Belgrave Electric Supply Company, 268.
Nonpareil Electric Syndicate, 447.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 625.—Vol. XXV. FRIDAY, MAY 9, 1890. Price Fourpence.

NOTES.

The decision of the Select Committee of the House of Commons in regard to the Central London Railway Bill shows that the various objections urged against the scheme by its thirty odd opponents were in the eyes of the Committee mutually destructive. The proviso that no prospectus is to be issued, nor any capital applied for, until the City and Southwark line has been for some time in operation, is an eminently reasonable one. Upon the degree of success which attends the working of these two London underground electrical railways, the immediate future of electric traction in this country will in a large measure depend; and it is not, therefore, to be regretted that the Committee thought fit to defer the commencement of the Central London line until the only other one of its kind has succeeded beyond question. Both the electrical and the engineering portions of the scheme are in good hands; and the promoters of the Bill are to be congratulated that "the precious plea of postponement" did not unduly influence the House of Commons Committee.

In spite of the very able statement of Mr. Fletcher Moulton, the deputation from electric lighting companies that waited on the President of the Board of Trade last Friday received but cold comfort. Sir Michael Hicks-Beach's assurance that the Board of Trade will not permit a local authority to use the powers given it "to keep the electric light out of its town" is hardly satisfactory in view of the fact that local authorities have been allowed to hold Provisional Orders for seven years without making use of them. The deputation were evidently of opinion that the obstructive tendencies of local authorities should be checked automatically by the insertion of suitable clauses in their Provisional Orders rather than by the spasmodic action of the Board of Trade. But, as we have already said, the deputation were bidden to be of good cheer, and trust to the benevolent intentions of the department over which Sir Michael Hicks-Beach presides.

Electric sparks, which but a short time ago were chiefly regarded as a source of amusement, have now been found capable of several useful applications. Not only have they, in the hands of Hertz and Lodge, contributed largely to the advancement of electrical theory, but they have shown themselves specially suited for the production of instantaneous photographs of rapidly moving objects. Mr. C. V. Boys, who has lately turned his attention to the subject, showed the results of his well-known manipulative skill to the Physical Society on Friday last. The successive forms assumed by moving water-drops were shown in an admirable series of photographs taken not only with a single slow spark, but even with the oscillating spark itself, a photograph being obtained at each oscillation. The periodical character of the spark is of course a valuable characteristic for purposes of this kind. The only marvel is that light, lasting for such a very short time, should be found sufficient to produce the chemical effects necessary for photography; although the suggestion of Lord Rayleigh, that it is to be accounted for by the richness of the spark in ultra-violet ray and to the absence of any absorbing lenses, seems to contain the solution of the difficulty.

The phenomenon of residual discharge which occurs with condensers has sometimes been attributed to an actual penetration of the electricity into the substance of the dielectric. M. Bouty, in a recent investigation of the subject, has experimented on mica condensers formed of very thin plates. It was assumed that the positive and negative electricities, soaking into the dielectric from the electrodes, would meet and neutralise each other if the plates were sufficiently thin. A constant current would therefore pass under the influence of a steady electromotive force, and the dielectric would behave like a conductor. It is a deduction from theory that for condensers having the same dielectric the product of the capacity and dielectric resistance should be constant. The experiments of M. Bouty appear, however, to disprove this law, which, as far as we are aware, has not before been put to any practical test.

About twenty volts were applied to a subdivided condenser in series with a graphite resistance of several hundred megohms, the current flowing being measured by the reading of a Lippmann's electrometer shunted to the latter. The current, although variable on first applying the battery, was found to become quite steady after two hours, and its value remained unaltered while the capacity was varied between one microfarad and a tenth of that value. As the resistance offered by the condenser was always very much greater than that due to the graphite, it seems necessary to conclude that the current is not due to the actual passage of electricity across the dielectric, since in that case the resistance of the condenser would have been found inversely proportional to the capacity. The delicacy of the tests may be judged from the fact that the

Digitized by Google

smallest current perceptible corresponded with a specific resistance of the mica equal in ohms to the resistance of a column of mercury one square millimetre in section and long enough for light to require 3,000 years to traverse it.

THE experiments seem to show that the conduction of dielectrics is due solely to extraneous surface leakage arising from imperfect insulation of the electrodes or to flaws in the material. M. BOUTY accounts for the phenomenon of residual discharge, which causes the variations in the current on first applying the battery, to progressive change in specific inductive capacity during that time. It, however, appears easier to follow MAXWELL in accounting for the separate effects by the simple assumption of a heterogeneous dielectric. In view of the great practical importance of insulators, it is desirable that these experiments should be repeated, for the results are at variance with recognised views.

THE Mutual Telephone Company certainly starts on its career with excellent intentions, both financial and electrical. Promotion money and commissions are to be unknown to it, and the long-suffering telephone subscriber is promised complete metallic circuits, an improved system of central exchange switching, and greatly reduced charges. Cheaper rates and an improved service are, of course, very attractive; but it remains to be seen whether the National Telephone Company, under the stimulus of threatened competition, will not cut the ground from under its rival's feet by the simple process of offering its clients still greater attractions. In this contingency the Mutual Company, even with the many advantages it possesses, will have a somewhat formidable task in front of it. However, as it is proposed to immediately commence operations in Manchester, the National Telephone Company's counterblast cannot be long delayed.

THE misfortune which has so persistently pursued the Maxim Weston Electric Company has culminated in something ap proaching a fiasco. By the latest balance-sheet of this Company, which will be found in another column, it will be seen that the Company's sole income during the past year amounted to the large sum of £41. 13s. for transfer fees and interest. It is worthy of note also, that the retiring Directors do not offer themselves for re-election, while the auditors do.

ELECTRICAL engineers in this country have frequently to complain, so we are given to understand, of the vagaries of fire insurance inspectors due to their lack of electrical knowledge. Much the same difficulty exists across the Atlantic; and the remedy arrived at there is simplicity itself, namely, the electrical educating of the inspector by the electrical engineer whose work he is to pass. Such, at least, is our reading of the following paragraph in our Boston contemporary *Modern Light and Heat*:—"A meeting is announced to take place between electrical men and insurance men in New York, to complete arrangements for a number of insurance inspectors to be examined and instructed by first-class electrical engineers, so as to be able to determine correctly the quality of all electrical work."

THE lecture on the remarkable repulsion experiments of Prof. ELIHU THOMSON which will be delivered before the Society of Arts on Wednesday next by Dr. FLEMING promises to be of considerable interest. These experiments have a most direct bearing upon alternate-current motor problems, and open a wide field for practical discovery. The apparatus exhibited by Prof. THOMSON at the Paris Exhibition has been lent to Dr. FLEMING for the occasion; and Mr. ERNST THURNAUER, the engineer of the European Thomson-Houston Company, will come over from Paris to assist in carrying out the experiments.

The City of London and Southwark Subway Bill.—This Bill was read a third time in the House of Commons on Wednesday last.

Newcastle.—The large gas lamps at the Cattle Market and the Central Station Square were replaced last week by arc lights, the current being supplied by the Newcastle and District Electric Lighting Company.

Proposed Spanish Submarine Cable.—Tenders for the laying of a cable connecting Spain with the isles of Puerto Rico and Cuba are about to be invited by the Spanish Government. The proposed cable will be one of the longest in existence.

Institute of Marine Engineers.—On Tuesday last Mr. R. E. Crompton gave his first lecture on "Practical Electrical Engineering," before the Institute of Marine Engineers. The second lecture, on the same subject, will be given on Tuesday, May 20th, at 7:30 p.m.

Southampton.—The Special and General Works Committee of the Southampton Harbour Board reported at the last meeting of the Board in favour of the adoption of electric cranes. This proposal gave rise to considerable discussion, and the matter was finally referred back.

Electric Traction in Coal Mines.—In the Richterschact pit, Laurahütte, the Allgemeine Elektricitäts Gesellschaft has just laid down at its own cost a mineral tram line. A similar course has been adopted by the Deutschen Elektricitätswerke of Aix-la-Chapelle at Antonienhütte.

Obituary. — Mr. James Nasmyth, the famous inventor of the steam hammer, died on Wednesday morning last, at Bailey's Hotel, Queen's-gate. Mr. Nasmyth was born in Edinburgh on August 19th, 1808, and he was consequently in his eighty-second year at the time of his death.

Public Building Lighting.—The electric lighting of New Scotland Yard, which is being carried out by Mr. A. A. Campbell Swinton, will require no less than 1,100 lamps, and the total length of wire both for electric lighting and communication purposes will amount to over twelve miles.

Eastern Extension, Australasia, and China Telegraph Company.—This Company announce that the laying of their new Sydney-Nelson cable has this week been successfully completed, thus duplicating the cable communication between Australia and New Zealand, and increasing the security of the service.

The Frankfort Exhibition, 1891.—We understand that the Managing Committee intend making a special display of the uses to which electricity may be put as a motive power, with a view of demonstrating the superiority of electric motors to steam engines for many purposes for which the latter are now employed.

The Electro-Harmonic Society.—The annual general meeting of this society will take place on Wednesday, May 21st, at 4:30 p.m., at 4, The Sanctuary, Westminster, S.W. The society, which commenced with 115, now at the close of the fourth season consists of 278 members. Fifty members were elected during the past year.

Telephonic Extensions in the North.—An important addition to the telephonic system in Scotland has just been provided by the completion of a system of telephonic communication between Edinburgh, Glasgow and Dundee. The new trunk wire is about 100 miles long, and is conveyed under the Tay by a cable two and a-half miles in length.

Digitized by Google

The Copper Market.—According to statistics furnished by Messrs. H. Merton, the visible stocks of copper on April 30th were 90,230 tons, compared with 124,447 tons on the same date last year, and 91,938 tons a month ago. The deliveries for the past month have been 10,050, compared with 11,535 tons a month ago, and 8,509 tons on April 30, 1889.

Eastbourne.—At the last meeting of the Town Council, a letter was read from the Board of Trade, stating that on the explanations forwarded in regard to special circumstances, they would now agree to a Provisional Order being granted to the Eastbourne Electric Light Company, at the maximum rate of 10d. per unit, as requested by the Electric Light Company.

The Ward Electric Car.—The Ward Electric Car Company announce that an experimental omnibus can be seen by appointment at their newly-opened premises in Dacre-street, Westminster, S.W. The Company have contracted with the Electrical Construction Corporation for their first line of electrical omnibuses, which will run between King's Cross and Charing Cross.

Royal Society.—The following Papers were down for reading at the Royal Society yesterday:—"On the Heating Effects of Electric Currents," No. 4, by Mr. W. H. Preece; "On Barometric Oscillations during Thunderstorms, and on the Brontometer, an instrument designed to facilitate their study," by Mr. G. J. Symons.—The annual *conversazione* of this Society will be held on Wednesday next.

Appointment Vacant.—The Council of the University College of South Wales and Monmouthshire are prepared to appoint a Professor of Mechanical Engineering in the new Department of Engineering of the University, with a stipend of £300 per annum. Further particulars will be found in our advertisement columns, and all information can be obtained from Mr. Ivor James, at the University, Cardiff.

The Telautograph.—We are informed that the Comptroller of Patents has decided that the autotelegraphic inventions of Professor Gray and Mr. Thomas O'Brien are practically the same, and has refused to grant a patent to Professor Gray unless he withdraws his principal claim, and inserts a disclaiming clause in the specification to the effect that his patent does not claim or cover anything that is described in the specification of Mr. O'Brien's patent.

Reduction of Telegraph Tariffs.—The River Plate Telegraph Company has reduced its charges from 30c. for 10 words and 10c. for each additional five words, and 10c. per code word to any telegraph station in the Argentine Republic. The Western and Brazilian line has also reduced its charges between Buenos Ayres, Europe, and New York; and the International Telegraph Company at Montevideo has reduced its tariff between that city and Buenos Ayres to 40c. for 10 words.

The Institute of Medical Electricity.—Viscount Templetown has accepted the chairmanship of this Institute, in the place of Mr. William Lant Carpenter, who, owing to ill-health, has resigned his office, to the great regret of all concerned. Lord Templetown is a well-known electrician, and has taken strong interest in the Institute of Medical Electricity since its inception. There is no doubt that under his rule the scientific thoroughness of the Institute will be maintained, and its usefulness further developed.

Hardingstone Local Board.—At the end of last month Major Marindin held an inquiry with reference to the Hardingstone Local Board's refusal to consent to the application for a Provisional Order by the Northampton Electric Light and Power Company. The Inspector's report is to the effect that the promoters have not shown sufficient cause for dispensing with the consent of the Hardingstone Local Board, and he recommends that the district of the Hardingstone Local Board be struck out of the area of supply scheduled to the Order.

New Telegraph Route between Bombay and Calcutta.—The opening of the Bengal-Nagpur Railway, says the *Indian Engineer*, will give a new telegraph route between Bombay and Calcutta. A copper wire is to be laid the whole distance (over 1,100 miles), and messages will be signalled direct, as is now the case between Bombay and Madras. The wire has already reached Nagpur, and it will soon be extended to Calcutta. It will greatly relieve the traffic on the existing lines, and messages passing between Calcutta and Europe *viâ* Suez will be more expeditiously disposed of.

Bolton.—A special meeting of the Town Council was held on Wednesday for the purpose of considering the advisability of applying for an electric lighting Provisional Order under the Electric Lighting Acts, 1882-88. Alderman Miles, Chairman of the Gas and Lighting Committee, moved the resolution, and in doing so said that at least thirty large towns intended to apply for Provisional Orders during the next Session; and seeing that a company (the Lancashire and Cheshire House-to-House Company) had applied for powers, the Gas Committee thought it best to get the matter into their own hands. After some debate the resolution was unanimously agreed to.

The McDougall Motor.—This motor is of the inverted horse-shoe type, with a Gramme armature. There is one point worth noticing in the McDougall motor, namely, the general use of mitis metal for the magnetic circuit. Recent experiments in Germany have shown that it is possible to secure a cast-iron of even better magnetic properties than most wrought-iron, and experiments tried on the mitis metal, of which this motor is constructed, have shown a similar result. Not only is it equal in magnetic permeability to forgings, but many specimens of it are distinctly better—in some cases by as much as 50 per cent. These valuable properties make mitis metal likely to take an important place in electrical manufactures, for the ability to avoid expensive tool work by making casts of such excellent magnetic material will go far towards compensating for the extra expense of the material itself.

Thermo-magnetic Apparatus.—The two following pieces of laboratory apparatus have been devised by J. Stefan to exhibit thermo-magnetic phenomena. The first, a thermo-magnetic pendulum, consists of a nickel segment attached to the end of a strip of brass, which is movable round a horizontal axis, and is provided above this axis with a sliding weight. When at rest the nickel segment lies between the poles of a horse-shoe magnet. On heating one end of the segment, however, that end immediately moves upwards, and if the heating is continued a regular oscillation may be started. The second piece of apparatus is merely a nickel disc which can rotate around an axis passing through its centre of gravity. The poles of a horse-shoe magnet cover a portion of the rim, and on heating another portion the wheel commences to rotate, and under favourable conditions can be made to revolve at the rate of 60 revolutions a minute.

The International Telegraph Conference.—A circular has been issued by a number of Manchester merchants calling attention to the meeting of this Conference next week, and stating that unless the mercantile community interests itself by making timely remonstrance with Government they may find the limit of code-words reduced to eight letters. They have also signed a memorial to the Manchester Chamber of Commerce requesting that representations may be made by the Chamber to the Postmaster-General that the British Government do not sanction any changes in the existing rules of the International Telegraph Convention which will lead to the curtailment of the use of legitimate words, not exceeding ten letters, of eight authorised languages.—According to the Berlin correspondent of *The Times*, Herr von Stephan, Imperial Minister of Posts, means to submit a proposal to the International Telegraph Conference for the adoption of a uniform international telegraph tariff.

The Wellingborough and District Tramroads Bill.—This Bill came last week before a Committee of the House of Lords. The objects of the Bill are to extend the lines of the Wellingborough Tramroads Company from Bozeat to Olney, and there to form a connection with the Midland Railway, and to run on from thence to Irchester and Higham Ferrars and Rushden. It is proposed to work the whole system by electricity. The only petition against the scheme was that of the South of England Telephone Company, who demanded that provisions should be inserted for the protection of their lines. Dr. John Hopkinson and Mr. W. H. Preece were called in support of the provisions

Digitized by Google

proposed by the Telephone Company. The Committee finally decided to pass the Bill with the insertion of the proposed clauses, with the addition that, if required by the Telephone Company, words should be added to the effect that the promoters should bear a share of the expense of protecting existing telephone lines.

Thermo electric Investigations. — Some experiments on thermo-electric currents between amalgamated zinc and zinc sulphate were recently described by Herr K. A. Brander. The primary object of the investigation was to determine the relation between the electromotive force developed and the difference of temperature between the electrodes. The electrodes, of amalgamated zinc, were placed in two vessels communicating by means of a syphon, and filled with a solution of zinc sulphate. One of these vessels was kept at the temperature of the place of observation, while the temperature of the other was gradually raised. The *Journal* of the Chemical Society says the author found that, within the limits of errors of observation, the electromotive force was proportional to the difference of temperature, until this difference exceeded 20·45° C., after which the electromotive force appeared to increase rather more rapidly than the temperature difference. Experiments show that concentration of the zinc sulphate solution increased the electromotive force.

The Board of Trade and Electric Lighting Companies.—In the House of Commons on Thursday last week Mr. Kimber asked the President of the Board of Trade whether, as the Board had struck out at the instance of local authorities Clause 6 of the Board's Model Order prohibiting a supply of electricity beyond the area of supply, he was prepared to make a similar concession to electric lighting companies; and whether he would grant to companies the same concession, namely, an appeal to the Board of Trade in the matter of compulsory works, which the Board made to local authorities at their recent interview with the officials of the Board of Trade on April 24th last. Sir M. Hicks-Beach, in reply, said that his answer to the first inquiry must be in the negative, seeing that the position of a company limited to an area, and possibly with other companies in adjoining areas, is distinct from that of a local authority having jurisdiction over their own local district, even though this should be larger than their area of supply. As regards the second inquiry, he was prepared to treat companies and local authorities alike.

Royal Institution.—At the general monthly meeting of this Institution, on Monday, May 5th, the following gentlemen were unanimously elected as officers for the ensuing year:—President, The Duke of Northumberland, K.G.; treasurer, Sir James Crichton Browne, M.D.; secretary, Sir Frederick Bramwell, Bart, M.Inst.C.E. The following Vice-Presidents for the ensuing year were also announced:—Sir Frederick Abel, Mr. William Crookes, Mr. Edward Frankland, Mr. William Huggins, the Right Hon. Earl Percy, Mr. Basil Woodd Smith, Sir James Crichton Browne, treasurer; Sir Frederick Bramwell, Bart., secretary. Prof. Tyndall was elected honorary professor of natural philosophy, and Lord Rayleigh was elected professor of natural philosophy. The annual report for the year 1889 testified to the continued prosperity of the Institution. The real and funded property now amounts to above £82,000, entirely derived from the contributions and donations of the members; 51 new members were elected in 1889; 63 lectures and 19 evening discourses were delivered in 1889; and a total of 822 volumes were added to the library in the year.

Wire Construction in Cities.—In a recent number of the New York *Electrical World* Mr. A. A. Knudson describes a system called the Aerial Conduit method, patented in 1881 jointly by Mr. O. F. Smith and himself. An ordinary I-shaped iron girder is employed, enclosed in a sheet-iron case in such a manner as to form a conduit with two compartments. The conduit is supported overhead on hollow wrought-iron pillars from 18ft. to 20ft. high, placed 60ft. apart. The structure is to be made ornamental; and the smaller size conduit, which is but 6½in. by 8in., will contain as many as 500 telephone or telegraph wires and 20 or more electric light wires. In distributing wires from the structure, it is intended to run the wires down the hollow iron pipes just below the flagstones of the sidewalk, thence through a pipe to the basement of buildings. By this method an important point is secured in the way of accessibility to any part of the line. When wires are to be placed inside, the doors are unlatched and slung down for the distance required and the wires or cable laid in, thus obviating the necessity of drawing them through conduits.

The Scharf Gas Battery.—The Scharf gas battery consists of a gas-tight vessel, preferably of cylindrical form, capable of holding the gases under very considerable pressure. The idea is to work with two gases in pairs, or with one gas and a liquid—one gas or liquid forming the positive, and the other the negative element in the cell. Among the gases of one class named by Mr. Scharf as suitable for his purpose are hydrogen, water gas, generator gas, coal gas, and all the vapours of the more or less volatile hydrocarbons of mineral oil. In the other class are placed air, oxygen, chlorine, fluorine, and the liquids hydrogen peroxide and nitric acid. Two typical gases for use in this way would be coal gas and oxygen, which would be compressed and stored separately. Each gas is admitted to one side of a carbon diaphragm, or rather, between two adjacent carbon diaphragms, contained in the vessel already described; and the plates of carbon are separated into pairs by alternate spaces filled with a gas and with asbestos saturated with acidulated water. All the intervals of even numbers in the pile would thus contain one gas, and all the others another of opposite electrical condition. In this way a pile of any number of cells might be built up.

Electromotors in Engine Works.—Messrs. Denny and Co., engineers, Dumbarton, have the tools in their pattern shop driven by a 20 horse-power electromotor. The dynamo is placed in the machine shop and driven from the ordinary shafting. From the generator to the motor in the pattern shop the current is conveyed through two cables about ⅜in. diameter. If this had not been done, a separate small engine and steam piping of great length would have been required. In the boiler shop of the same firm, says *Industries*, there is a still more interesting example of the application of electricity as a motive power. This is Rowan's patent electric boring machine, for drilling the rivet holes through boiler shells *in situ*. Anyone who has watched drilling tackle at work, especially in shipyards, must have noticed how much time was absorbed in fixing the clamp into position. Rowan's electric borer not only has a small motor to drive the drill, but holds itself up against the plate by means of a pair of powerful electro-magnets. Messrs. Denny are about to put electromotors to other uses in their yard, amongst the earliest of which will be the driving of all the sewing machines in their large upholstering department, at present driven by the feet of the female operators.

The Silvertown Dry Cell.—The following are the averages of a number of tests on a new dry cell now being manufactured by the India Rubber, Gutta Percha and Telegraph Works Company:—

Cell.	E.M.F.	Internal resistance.	Hours working through an external resistance of 7 ohms before falling to half potential.
Large size...	1·5	·528	369
Small do....	1·51	·336	123

The weight of the cells when complete is, in the case of the large size, 4½lb., and for the small size 2lb. 7oz. The cell is specially designed for use where the battery is liable to shaking or rough handling, such as on board ship, for field telegraphy, and similar work, where it would be found inconvenient to use the ordinary cells. Care should be taken in mounting a battery of these cells to prevent one cell from touching another, and they should stand upon a base of some insulating material, such as glass or dry wood; and for efficient working this cell is not recommended to be used in positions where the temperature is high. When the cell appears to have been worked out it is, as a rule, only necessary to fill it up with a saturated solution of sal ammoniac and let it stand for some time, when the solution may be poured out and the cell wiped dry at the top; it will then be found to have recovered.

THE EDINBURGH EXHIBITION.

The Edinburgh International Exhibition, as we announced in our last issue, was opened with due ceremony on May 1st by the Duke and Duchess of Edinburgh. The many thousands who have already passed the turnstiles have no doubt set at rest any uneasiness which may have existed in the minds of the executive committee on the score of the financial success of the Exhibition; and if the visitors throng for the most part in the Concert Hall, or around the band-stand in the grounds outside, it is certainly not for want of more solid attractions within the buildings. The display of electrical apparatus, for instance, is very creditable, and, including as it does examples of all the more important applications of electricity, is well calculated to impress even the most casual observer.

The selection of a site more than a mile distant from the centre of the city would probably have militated somewhat against the success of the Exhibition had not the means of communication been so complete. As it is, in addition to being thoroughly accessible, the site at Merchiston is picturesquely situated, and is of ample size, extending to some 50 acres, with a further large reserve of 40 acres, and will, moreover, shortly be placed in direct railway communication with the Forth Bridge. The Exhibition buildings, which are almost entirely of wood, and painted with a variety of hues, comprise the Main Building, 700ft. long by 250ft. wide; the Machinery and Electric Hall, 680ft. by 150ft.; a fine Concert Hall, Picture Galleries, a Railway Court, and a French Electrical Annexe. In the grounds, which are very extensive, there are, or rather we should say there will be, several interesting applications of electricity. A telpher line, about half-a-mile long, is being laid down by the United Electrical Engineering Corporation, who are also responsible for the electric railway which is to connect the Exhibition stations of the Caledonian and North British Railways; and, as we have already announced, four electric launches, engined by Messrs. Immisch and Co., will ply between Edinburgh and the Exhibition along the Union Canal.

The lighting of the buildings and grounds, which has been entrusted to the Brush Company and to Messrs. King, Brown, and Co., has been very creditably carried out; and although all the circuits were not being run at the time of our visit, there was no lack of light. The arc lighting is entirely in the hands of the Brush Company, whose installation comprises 365 2,000 candle-power lamps, 283 of which are used for interior illumination, and 82 for the lighting of the grounds, where the lamps are for the most part arranged in groups of three on 65ft. plain iron tubular masts. These masts have a graceful appearance; they stand without stays, and have all the electrical conductors and necessary gear for raising and lowering the lamps contained in the interior of masts. To avoid anything like a complete breakdown in any one part of the Exhibition, the circuits have, as usual, been arranged so that alternate lamps are fed from different dynamos. The leads from the dynamos are carried to a switchboard, where they terminate in pairs of contact hooks; the terminals of the various circuits consist of pairs of stirrups, so that it is only the work of a moment to couple any dynamo to any circuit. The Concert Hall, Reception and Refreshment Rooms are lighted by incandescent lamps of 200, 50, and 16 candle-power, the larger ones being Sunbeams. This part of the lighting is in the hands of Messrs. King, Brown, and Co., and is very effective. The dynamos and engines engaged in the lighting are all situated in a fine open space, 120ft. by 80ft., in the centre of the Machinery Hall, and form the most striking feature of the Exhibition. The first thing which attracts attention are a pair of magnificent horizontal compound engines by Messrs. Robey and Co., of Lincoln, one of which is capable of developing 320 and the other 260 horse-power. The larger of these engines is fitted with trip expansion gear, and has a fly-wheel 15ft. in diameter; and the lesser has a fly-wheel 12ft. in diameter. These engines, which have been especially made for the Exhibition, are employed in driving the whole of the arc dynamos used in lighting both the Exhibition buildings and the grounds. The power is transmitted by ropes to counter-shafting, and thence by belting to the dynamos. Behind these engines is situated the boiler-house, in which there is a battery of five Galloway boilers, of a combined capacity of 2,500 horse-power. From these boilers practically the whole of the steam required for driving purposes is supplied, at a pressure of 110lb. to the square inch. Messrs. King, Brown, and Co.'s incandescent light dynamos are driven direct through belting by two fine engines of the Westinghouse type, which have been specially constructed for the occasion by Messrs. Alley and Maclellan, of Glasgow. One of these is of novel design, and its performance will be closely scrutinised, inasmuch as an unusual degree of economy in working is anticipated.

Turning now to the electrical exhibits, we shall confine ourselves in this preliminary notice to making a brief mention of those exhibits which are actually complete, and hope in subsequent issues to describe the more important and interesting in detail. One of the most interesting and valuable exhibits in the Electrical Section is that of the British Post Office. Not only does the Post Office differ from a large number of electrical exhibitors in having its stall absolutely complete, but the value of its exhibit is considerably enhanced by the simple but useful addition of a brief clearly-printed explanatory ticket which is attached to every piece of apparatus. The catalogue, which, we may remark *en passant*, is hardly as reliable a guide to the Exhibition as could be wished, in most instances merely informs its readers that such and such a piece of apparatus is a dynamo, transformer, or secondary battery, as the case may be, leaving them to evolve from their inner consciousness the probable use of these mysterious contrivances. We would suggest, therefore, that other electrical exhibitors would do well to imitate the Post Office, and ticket their apparatus with explanatory labels for the benefit of the non-technical public. On the Post Office stall there are to be seen examples of almost every type of telegraph instrument in use, or formerly in use, in the United Kingdom, ranging from Cooke and Wheatstone's earliest needle telegraph of 1837 down to the Wheatstone automatic of to-day. Close to the Post Office stall, and adjoining the French Annexe, is the fine exhibit of the Eastern Telegraph Company, which comprises, amongst other things, the latest and earliest types of Sir William Thomson's syphon recorder, a Saunders lightning guard, and a model of the improved bow-gear fitted to the Company's cable steamer "John Pender." The Consolidated Telephone Construction and Maintenance Company make an excellent display of their well-known domestic and portable telephonic apparatus. The young firm of Prentice Napier and Co., of Stowmarket, show four moderately-sized well-finished dynamos, in which all wires are protected from dust and moisture by metal casings. One of the dynamos is connected direct to a high-speed engine, by Easton and Anderson, of Erith. Messrs. Ernest Scott and Co., of Newcastle, make a very good display with direct-coupled dynamos for ship-lighting; they also exhibit a small 10-unit "Tyne" alternator and some "Tyne" transformers. A noticeable feature of Messrs. King, Brown and Co.'s stall is a very compact compound engine, coupled direct to a 200-light dynamo, running at 300 revolutions. We may mention here that Messrs. King, Brown, and Co. have one or two motors driving exhibits in various parts of the building; and it is to be hoped that several more will be installed before the Exhibition closes. The India Rubber, Gutta Percha, and Telegraph Works Company show a fine compound engine, by Messrs. Musgrave and Sons, of Bolton, coupled direct to a fine "Silvertown" dynamo. The exhibits of the Electric Construction Corporation, and of Messrs. Immisch and Co., promise to be the most interesting of their kind in the Exhibition. The Electric Construction Corporation show a fine accumulator car, with motor and cells complete; a 10-unit alternator, with engine; a large variety of secondary batteries, and a set of the ingenious automatic devices employed in the E.P.S. system of distribution. Messrs. Immisch will exhibit tramcar, launch, mining, and other motors, and an "Ingersoll" percussion rock-drill worked by an Immisch motor.

The display of electric light cables and wires is very complete, most of the leading firms exhibiting. Minor electrical apparatus, such as battery jars, insulators, bells, switches, cut-

Digitized by Google

outs, arc-light carbons, artistic fittings, &c., are very much to the fore, the exhibits being generally more forward than those of the heavy engineering firms. The display of electrical measuring instruments is not so good as might have been expected, though Mr. James White, of Glasgow, has a fine case containing three of Sir William Thomson's current-balances, a vertical electrostatic voltmeter, a multicellular electrostatic voltmeter, a magneto-static current meter, and an ampere-gauge; and away in the North Court Prof. James Blyth has another case containing current-weighers and other instruments.

Apart from the fine engines engaged in driving the electric light dynamos, and the various engines to be seen on exhibitors' stalls driving dynamos direct, there are comparatively few steam-engines in the Machinery Hall. Messrs. Ruston, Proctor and Co. exhibit half a-dozen of their well-known engines, including a 16 horse-power compound semi-fixed engine, suitable for temporary electric lighting work. The display of gas and petroleum engines, on the other hand, is remarkably good, a fact which has been particularly noticeable at all recent exhibitions. In addition to the several engines in use in various parts of the Exhibition for driving exhibits, Messrs. Crossley Bros. show no less than twelve "Otto" engines, ranging from 33 horse-power to ½ horse-power. They also exhibit a 10 horse-power high-speed engine, designed specially for electric lighting work, the running of which is so even as to render unnecessary the heavy fly-wheel disc usually employed when a dynamo is driven by a gas-engine. Messrs. Dick, Kerr, and Co. show six of their "Griffin" engines, ranging from 12 horse-power nominal to ½ horse-power nominal. The two single-acting vertical engines of 1 horse-power nominal and ½ horse-power nominal respectively which this firm show are combined with water-tank on one base, and have a very compact and workmanlike appearance. Messrs. Priestman Bros.' exhibit is intended to show a complete private electric light installation, worked by an oil engine, and comprises a 5 horse-power nominal and a 2 horse-power nominal engine, a 2-unit "Tyne" compound-wound dynamo, accumulators, and other accessories.

From this rapid glance at the principal exhibits it will be seen that the display in the Electrical Section is fairly representative and comprehensive; and, as soon as the exhibits are all in their places and the electric tramcars and launches are running, and electric welding, electric tanning, and the Elmore process are to be seen in operation, it may be anticipated that the Machinery Hall and the French Electrical Annexe will attract their due share of the visitors who throng to the Exhibition. The idea of the present Exhibition originated, we believe, with Mr. A. R. Bennett; and the energy which has characterised the proceedings of those who undertook to carry out the scheme has certainly resulted in bringing it to a successful issue.

THE WALLER-MANVILLE SYSTEM OF ELECTRIC TRACTION.

The opposition that any overhead system of urban electric traction is certain to meet with in this country from local authorities, landowners, and others interested in preventing the obstruction and disfigurement of our streets by poles and wires renders it very desirable that English electrical engineers should devote their attention to overcoming the defects that have hitherto militated against the general adoption of the accumulator and conduit systems. As regards accumulators, the skill and money which have been lavished on them during the past three or four years have, indeed, transformed the accumulator car from an expensive toy into a commercial possibility. But although a storage cell has been evolved which is capable of withstanding with a tolerable degree of success the trying mechanical and electrical conditions of tramcar work, neither its output for weight nor its durability have been so greatly increased as to render accumulator traction an altogether satisfactory solution of the question. Neither can any conduit system which has been introduced up to the present be said to have proved an entirely satisfactory substitute for overhead wires. If a closed conduit is used, complicated apparatus must be provided for temporarily bringing a surface rail into circuit during the passage of the car over such rail. In all "open" conduit systems hitherto tried the conductor is buried in the conduit, and cannot be got at without considerable difficulty. In some systems a bare rigid conductor is used, supported at short intervals by separators, the current being collected by means of a brush of some description dragged upon the conductor, and pressed thereon either by its own weight or by means of springs. In other systems of open conduit, such as the Lineff, an insulated conductor is used having bare contact points attached to it at intervals. A flexible band of some description (of a greater length than the distance between the contact points) is suspended from the car so as to be always in contact with one or more of these points.

To overcome in some measure the defects of bad connection between the car and the conductor, difficulty of repair, poor insulation, &c., is the main object of the Waller Manville system. The improvements proposed relate entirely to mechanical details, and the system is consequently applicable to any known method of electrical distribution.

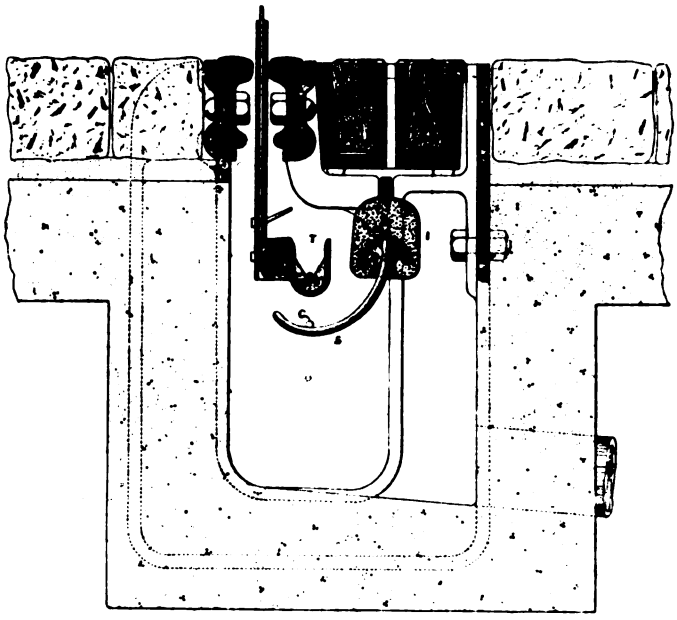

FIG. 1.—Waller-Manville System. Single Conductor. Cross-section through Hatchway.

The essential feature of the system is the employment of a flexible conductor sufficiently small to permit of its being placed in, or withdrawn from, the conduit through the slot. The conductor being flexible, the supports can be at long intervals of about 30ft.; and can therefore be placed in side openings to the conduit itself. By this means space is provided for large and efficient oil insulators. Removable covers are provided to these side openings or "hatchways," giving ready access to the insulators. The insulators are mounted in such a manner that on removing the cover they can at once be lifted out. The collecting arm is designed so that the shank can be withdrawn through the slot, and the collector proper (or brush) through any hatchway. Under ordinary conditions the conductor simply rests on supporting arms without being attached thereto. When it is necessary to firmly attach the conductor to its support, as, for instance, on sharp curves, absolute flexibility is still maintained, as the supports are so designed that whilst rigidly resisting either a longitudinal or a lateral strain, the same freedom of upward movement is allowed as in the case of the conductor itself when unattached. Simple automatic apparatus is provided at intervals to maintain a constant strain upon the conductor. The current is collected by means of a U-shaped collector in which the conductor runs; the collector lifting the conductor off the ordinary supports during its travel, and, in the case of those supports to which the conductor is attached, lifting the support itself.

Digitized by Google

A reference to the annexed drawings will explain the arrangements adopted in this system. Fig. 1 is a cross-section through a hatchway, and shows the ordinary form of curved supports

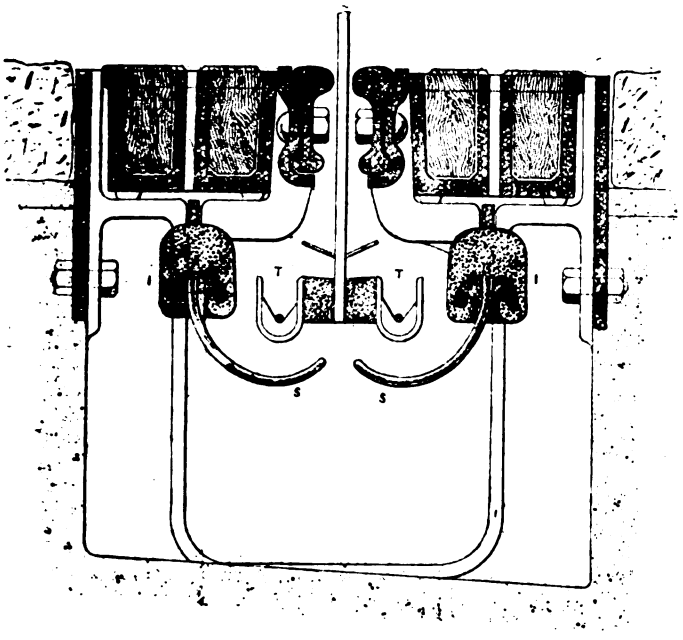

Fig. 2.—Waller-Manville System. Double Conductor. Cross-section through Hatchway.

on which the conductor C rests, and the moulded mica oil insulator I to which this support is attached. The conductor is shown lifted off the support by the collector T. Fig. 2 is

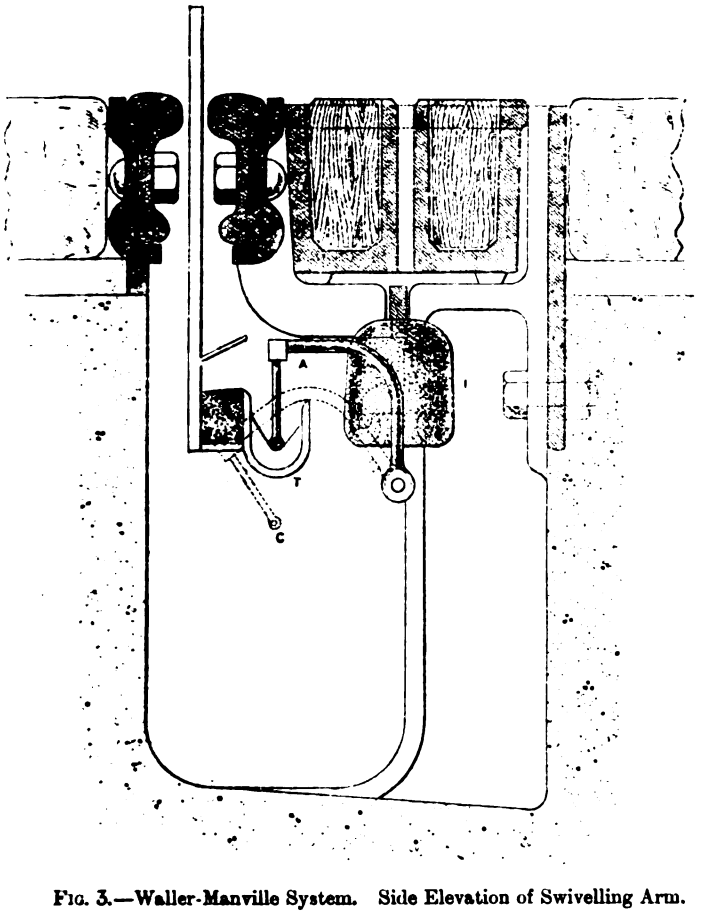

Fig. 3.—Waller-Manville System. Side Elevation of Swivelling Arm.

similar to Fig. 1, but shows the arrangement for two conductors in the tube. In Fig. 3 we have a side-elevation of the arrangement adopted at sharp curves, and which consists of a swivelling arm mounted on oil insulators. It will be observed that the conductor is held by this swivelling arm A, both being lifted by the collector, thus maintaining the flexibility of the conductor as regards upward movement, while rigidly resisting either a longitudinal or a lateral strain. Figs. 4

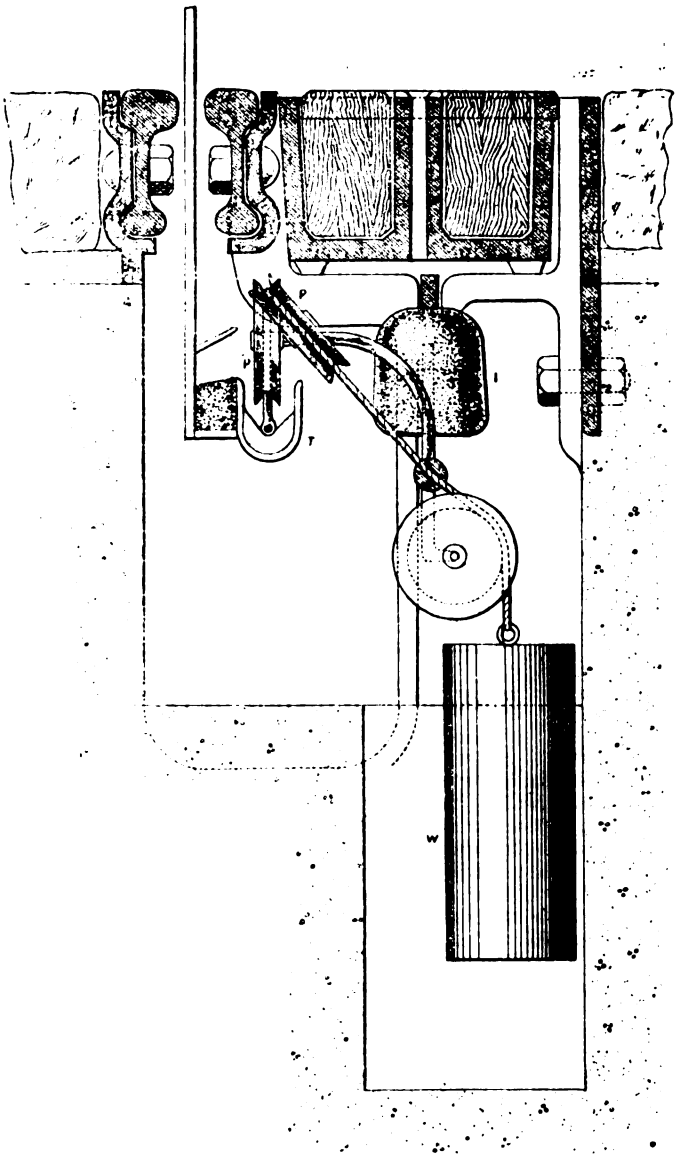

Fig. 4.—Waller-Manville System. Side Elevation of Straining Gear.

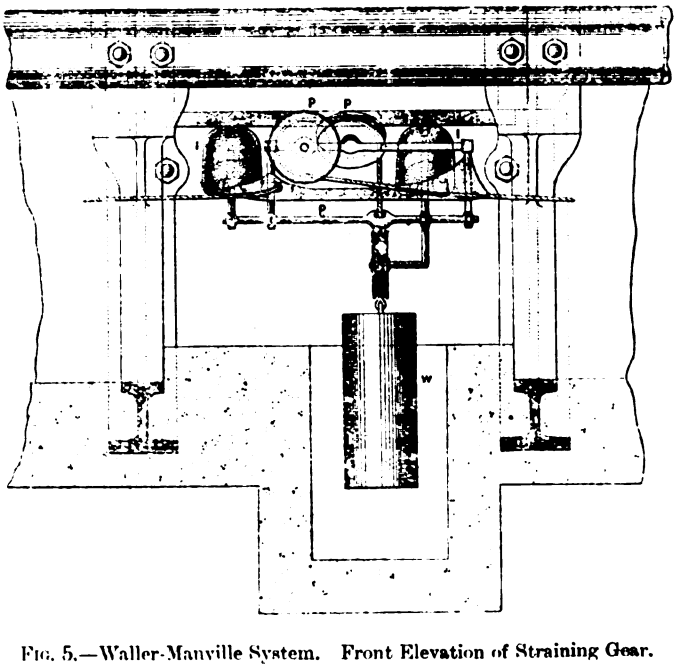

Fig. 5.—Waller-Manville System. Front Elevation of Straining Gear.

Digitized by Google

and 5 show respectively a side and front elevation of tension or straining gear. This consists of a gun-metal plate, P, mounted on two swivelling arms, and supported by oil insulators, I I, and provided with small pulleys, *p p*, so arranged that the conductor, or cat-gut cord in continuation of the conductor, is led to one side, so that a balance-weight, W, can be attached thereto. This weight serves to keep the sag of the conductor between its supports constant in all changes of temperature. As the pulleys are arranged on the swivelling arm, the whole apparatus is free to lift in a similar manner to the single swivelling arm, the conductor being led through an eye in the shaft on which the apparatus revolves; the upward or downward movement of the tension frame in no way affects the length of the conductor, and consequently no resistance to this movement is caused by the weight of the counter-balance. This tension-gear would only be required at long intervals, occurring, say, every quarter of a mile.

Of the practical value of these devices, it is, of course, impossible to speak with confidence until they have been actually tried on a commercial scale, which, indeed, we understand will shortly be the case. The method of effecting contact between the conductor and the collector, however, seems likely to prove very effective; and the employment of large oil insulators at long intervals will certainly tend to increase the working insulation of the line, so that, apart from its ingenuity, the system devised by Messrs. Waller and Manville contains several elements of practical success.

ELECTRIC TRACTION DATA.*

BY A. RECKENZAUN.

Of the various questions connected with electric traction the branch of which I have the honour of calling your attention to to-night, appears to me fundamental to a complete knowledge of the subject. It relates mainly to tractive force and mechanical resistances on tramways. It is a subject which is not as fully appreciated by electrical engineers as it should be, although it forms the very basis of street locomotion; and I venture to say that future improvements in the economy of electric traction will in a large measure depend upon minute attention to details relating to this branch of the science. The very existence of tramways as substitutes for the common road is concentrated in one point, viz., the reduction of tractive resistance to a minimum.

It is a well-known fact that the traction expenses on horse tramways constitute about two-thirds of the entire working expenses, and it has long been the aim of engineers to find an economical mechanical substitute for animal power. Electricity has found great favour with tramway men in the United States, and there is every probability of similar developments in Europe at a not distant date. Improvements can only be brought about by experience, and experience must be gained in actual practice and by careful observation. These, again, can be supplemented by data obtained from those who preceded us; and it is my intention to bring, in a condensed form, such data, from which you will be able to draw your own conclusions, and which will guide you in future and progressive efforts.

In order to provide facility for traction, we must have a solid permanent way, and excellent rolling surfaces. The practical value of a good rolling surface can scarcely be over-estimated. The rails must be rigid, parallel, and fixed to solid foundations. In America flat step rails without grooves are used; these offer less resistance to traction than grooved rails; but, as a rule, they are not so solidly laid as English rails. According to Mr. D. K. Clark, the resistance to traction on an ordinary railway may be as low as 6lb. per ton; but so low a resistance cannot be obtained with grooved rails, which are exposed to the incidents of mud, grit, stones, and dirt, and which, moreover, have frequent and sharp curves.

Mr. Henry Hughes deduced from experiments on tramways a tractive resistance of about 26lb. per ton; often more, occasionally less. Such high resistances as these are readily accounted for when it is considered that the flanges of the wheels frequently take a bearing on the bottom of the grooves, or on the dirt embedded therein, at the same time that the wheels roll on the surface of the rail; for thus the wheel rolls on two different radii simultaneously, and grinding of surfaces in contact must result. It may also occur that one wheel is running on its proper bearing surface, whilst the other, belonging to the same axle, has its flange touching the bottom of the groove, when by virtue of different circumferential velocities additional friction is introduced. Sometimes the rails are a little out of gauge. All these circumstances augment the tractive force requisite with grooved rails. The horse, if it could speak, would be a good witness, but failing his verbal evidence, the dynamometer has been consulted. Better than the mechanical dynamometer, however, is the ammeter. A dead-beat ammeter indicates instantly the slightest variations of tractive resistances; and I venture to say that it will be through the judicious and more frequent applications of this instrument that material improvements both in the permanent way and in the rolling stock of electric tramways will be effected.

Probably the most interesting and complete tests with horse cars were those made by M. Tresca. He proved, experimentally, that the groove in the rail was the direct cause of a large portion of the resistance to traction. An ordinary car with its four flanged wheels was propelled over the tracks of the Paris-Versailles tramway, and it was found that the average tractional resistance amounted to $\frac{1}{100}$th of the gross weight, or 22·4lb. per ton. Subsequently two of the flanged wheels, both on one side of the car, were removed and replaced by flangeless wheels, when the resistance, all other things remaining the same, amounted to only $\frac{1}{177}$th of the weight, or 15½lb. per ton. The gross weight of car and passengers was 5·67 tons. These experiments show conclusively that at least half the power is wasted in friction between the sides of the groove and the wheel flanges.

The force required to start a tramcar and to get up speed is necessarily greater than the force required to maintain a given speed uniformly. It was found that the starting force is from four to five times that necessary for running on the level road. Curves also increase the resistance very much. In dry weather, on curves of 50ft. radius, the resistance to traction is doubled, and on those of 35ft. radius trebled; but when the rails are wet, this resistance, due to curvature, is considerably reduced. Water, plenty of water, on the rails acts as an efficient lubricant, and you will see by statements later on the general effect of wet rails. Short wheel bases, bogies, or radiating axles, render motion on curved rails easier, and flexible axle boxes are now greatly favoured, especially in the United States, for the same reason.

The effect of gradients is a matter of simple calculation. It is the maximum gradient on a given line which determines the size and power of the electric motor. Allowing 22·4lb. tractive force per ton, we should have to exert a pull of 134·4lb. with a six-ton car on a level road. This, at the rate of seven miles an hour, or 616ft. per minute, would give us 2·5 horse-power effective on the axles. If we have to overcome a gradient of 1 per cent., or 1ft. in 100, the resistance due to gravity will also be 22·4lb. per ton; therefore we shall require about 5 horse-power to pull this car up a gradient of 1 in 100. With a 2 per cent. rise the power will be three times as great as on the level, and, roughly speaking, each per cent. of grade demands as much energy as the propulsion of a given weight on a horizontal road if the speed is to be constant. On steep gradients, however, it is customary to run slower, whereby some of the energy is saved at the expense of time.

The time at our disposal will not permit of descriptions of particular systems of electric traction, nor of the relative merits of each, and we shall confine ourselves entirely to statistics on tractive force, no matter how this force is transmitted; and we shall merely consider the question of moving a given load on a given track by means of the electric current. In order to ascertain the amount of energy used on electric cars I have made, in conjunction with the Electric Car Company of America, a long series of systematic tests both on an experimental track built for this purpose, as also on the public roads under all sorts of conditions of traffic. Whilst on the experimental track we could run at any speed we liked, and without stoppages; on the public streets we were confined to the speed of horse cars in front and behind us, besides taking up and putting down passengers and regulating our vehicle to the general traffic of some of the busiest streets of Philadelphia.

This experimental track was laid in an irregularly shaped yard as shown on the diagram No. 1, and it was intended to represent as difficult a line as is likely to occur in actual practice. Its entire length was 1,005ft., the ends being so joined that the cars could circulate continually. Five and a quarter journeys round this track represented a mile run. There were four curves, two of 50ft. radius, one of 33ft. and one of 100ft. Tangent with the 33-foot curve was a gradient of 4·98 per cent. rise, which descended on the other side at the rate of 5 8 per cent., and joined the curve with a radius of 100ft. On this track we carried out tests and recorded observations which may be counted by the hundred thousands. The following figures relate to experiments made with a car in the autumn and winter of 1887-1888. The vehicle was an ordinary 16 foot two-horse car, with two axles, one motor, and a set of storage batteries. It weighed, with several men on board, 5·3 tons; its wheel base was 6ft., and one axle only was driven by an electric motor with intermediate spur gearing.

The rails were the ordinary American flat rails, grooved only at and near the curves, which represented a large percentage of the

* Paper read on Wednesday, April 30th, before the Old Students' Association of the City and Guilds of London Institute.

Digitized by Google

entire track. With a set of 84 cells of a nominal capacity of 150 ampere hours, this car made 230 trips round this track, representing an aggregate of 43·8 miles with one charge of batteries. The car was only stopped and started fourteen times. The actual running time was 6¼ hours, giving an average speed of seven miles an hour.

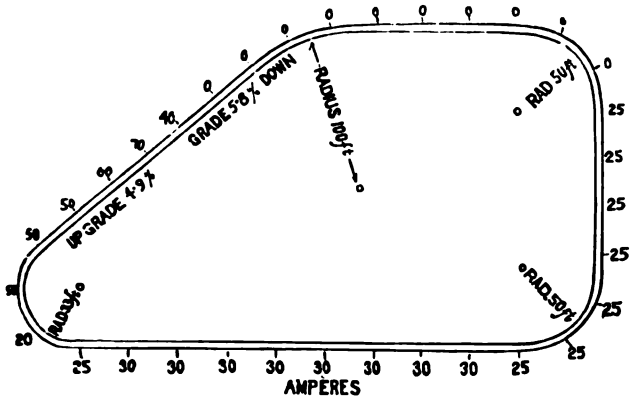

Fig. 1.

At the commencement the electromotive force of the cells on closed circuit was 160 volts, and at the end 145·2 volts, the average from actual measurements was 157 volts. The maximum current used on the steepest grade was 70 amperes at starting; on

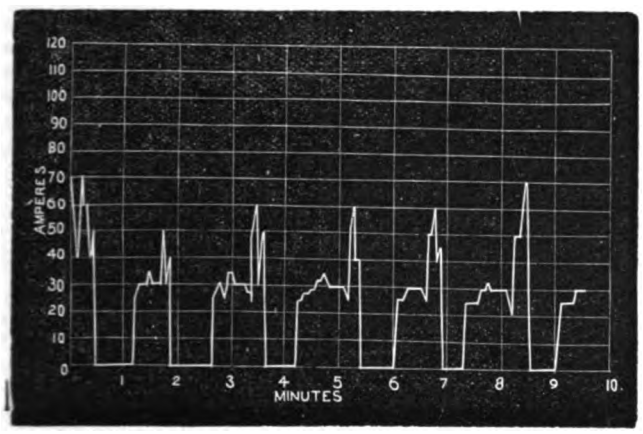

Fig. 2.

the curve or grade it rose to as much as 120 amperes. The average current consumed was 22 6 amperes, which corresponds to 141 ampere hours taken out of the battery. The current on the level road fluctuated between 18 and 25 amperes. The diagram No. 1 representing this track has marked upon it the current rates used at the various points of the journey. It will be observed that the car ran by momentum during a considerable portion of the journey, this momentum being acquired during its downward movement upon the 5·8 per cent. gradient, the brake being only slightly applied, and the stoppages during this experiment, as I have said, were few.

A mean of 4·75 electrical horse-power was thus expended, giving a consumption of 29·69 horse-power hours supplied by the battery; and the maximum energy given off at any moment was 10,500 watts, or 14 electrical horse-power. Allowing an average efficiency of 75 per cent. in the motor, and 85 per cent. in the gearing, we obtain a total efficiency of nearly 64 per cent. between the motor terminals and the axle, or about 3 horse-power available for traction. Thus the mean tractive force throughout the 43·8 miles run was 160lb., or about 30lb. per ton. This is very low, considering that out of the entire distance we had only 21 miles of tolerably level track, the rest being made up of 3·4 miles of 33ft. curves, 7·07 miles of 50ft. curves, 3·64 miles of 100ft. curves, and 4·05 miles of ascending grades of 4·98 per cent. On the other hand, there were 3·8 miles of descending grades of 5·8 per cent., which furnished momentum right along the 100-foot curve until the car passed completely into the upper 50-foot curve on the right hand side of the diagram. Converting the work into ton-miles, which is probably the most rational way of comparing figures, we get $5·3 \times 43·8 = 232·14$ ton-miles at an expenditure of 29·69 horse-power hours, and this gives nearly 7·78 ton-miles per horse-power hour. We have obtained much better results than this with a subsequent car containing various improvements, and, on one occasion, this larger car made 63 miles on the experimental track, each horse-power hour producing 10·9 ton-miles; but these are exceptional feats, and our present object is to consider practical results corresponding with everyday work—industrial results, in fact.

Three men, each well trained for his work, were necessary for these tests, and their respective duties were as follows:—One man took charge of the switch in front of the car and the hand-brake; in fact, he performed the ordinary function of a driver, taking care that the car moved at regulation speed on the level, that it did not "race" down grades, nor go too slowly up the inclines, and that it took the curves with safety. The second man, with a timepiece in his hand, counted the number of round trips and recorded the same; he also took voltmeter readings at equal intervals. The third attendant had the more difficult task of reading the deflections on the ammeter and writing down the values. In order to ensure uniformity in the time between each reading, and also take as many readings as possible, one has to learn to write down a certain number of figures in a given time, putting down ciphers, to fill up time when the ammeter needle is at zero. The number of observations written down during the 43-mile test was close upon 7,500, or one reading every three seconds. Considering the rapid variations in the current on uneven tracks, it is very important that readings are recorded at the shortest possible intervals in order to arrive at a correct average. The specific gravity of the cells was tested before starting, when they were fully charged, and it averaged 1,186 degrees. At the end of 6¼ hours, when the cells were practically discharged, the density fell to about 1,126 degrees. The accumulators were then recharged for six hours at the rate of 30 amperes when the electrolyte assumed its original specific gravity. It is impossible to keep the acid in every cell at the same density, there are always slight differences, and we had to take the mean of the entire number of cells to ensure accuracy. Diagram No. 2 represents the currents used during six journeys round the experimental track, and this was virtually repeated throughout the tests, except when stopping and starting. Now compare this with diagram No. 3, showing the current variations out in the crowded streets. You will observe a number of tall narrow peaks running down to the zero line at frequent intervals. During these intervals the car was either stopping or running by momentum. The vertical lines in this diagram represent minutes and seconds, and the horizontal lines amperes measured on the car during the entire journey from 23rd-street to the Exchange in Philadelphia and back to the Grayaferry depôt, and from thence again to its starting point,

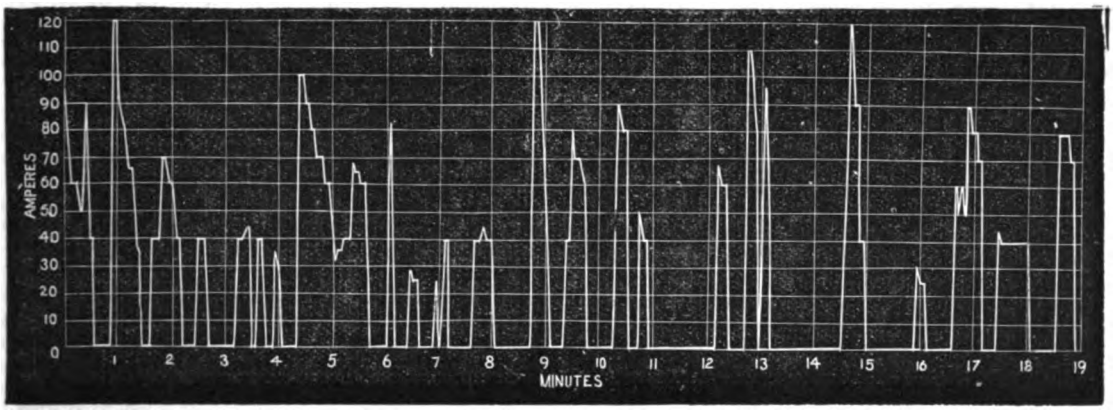

Fig. 3.

Digitized by Google

a distance of about seven miles. Every corner on this diagram represents a movement of the switch by the driver.

The switch was constructed to throw the various distinct coils on the field-magnets of the motor into parallel or in series, or into several intermediate steps, and these steps can be readily detected on the sharply defined junctions of the lines showing amperes. The average current consumed throughout this round trip, down town and back to the depôt, amounted to 31 amperes. The weather was dry, windy, and the road very dusty. Allowing for this, as well as the frequent stoppages and slowing down in order to keep pace with the horse cars on the same line, it appeared that there must have been some waste of energy. The diagram shows that there was a continuous effort of getting up great speed at one moment and slowing down the next. It shows that the driver was somewhat nervous and inexperienced to driving in the public streets, hence the frequent alternate use of high currents and brake. The gradients on this road are not very severe, the heaviest is about 4 per cent., and several of 2 and 3 per cent. Calculating as before, and allowing the same efficiency, we should get an average tractive force of 39lb. per ton. The car in this case carried 23 passengers one way, and 30 on the return journey, giving a mean load of 7 tons.

Numerous journeys were made through the city with this car, and some days after the above event I took again careful readings; the driver was more experienced, less nervous, never used the utmost electrical power at his disposal, and the average current during two round trips came to only 23·11 amperes,—25 per cent. less than formerly, under similar conditions of load, speed and weather. Although the average height of the peaks was less in this case, the number of them was nearly the same, and the gaps representing periods when no current was used gave, on being added up, 45 per cent. of the total. Thus for nearly half the time the car was running by momentum alone. It must be remembered that every few hundred yards there is a street crossing those we ran on, and all these streets have their tramways, so that for common safety it was necessary to slacken down at each square or block of buildings, even when other traffic and passengers did not impede our progress. These diagrams teach us two important lessons; one is, that a skilful driver can economise energy to a large extent; the other, that proper appliances for regulating the power within a wide range are a distinct advantage.

After a good shower of rain the tram rails assume a tolerably clean appearance; the mud is then easily squeezed out by the flanges of the car wheels; thus I have observed that during or immediately after a rainfall, the energy necessary for propelling a vehicle is considerably less than in dry weather. There is a positive saving of power amounting to from 15 to 50 per cent. with clean wet rails. By careful observations we were enabled to record the effect of various comparatively small obstacles on the rails, the ammeter showed the minutest variations in tractive force; it is far more reliable than a dynamometer, since it has neither friction nor momentum.

Snow is the greatest enemy of tramways, it offers the greatest resistance to traction. Anticipating snow storms, which occur rather frequently in some parts of the States, we fitted the experimental car with a snow plough and wire brushes. The plough shears were supported by a balanced frame underneath the front platform of the car. These shears could be raised and lowered by foot pressure. Behind the plough shears, and just ahead of the front wheels of the car, were brushes made of steel wire, and these were kept scraping over the rails by their own weight. The plough served the purpose of removing the bulk of the snow, and the brushes swept the rails and grooves clean in front of the wheel flanges. One day when it snowed very hard, and when the rails were covered about a quarter of an inch deep, we ran the car out upon the experimental track, using in the first instance merely the wire brushes and a little sand on the steepest gradient. It took 2min. and 8sec. to run once round the track, which was soon cleared of snow, taking a mean current of 50 amperes. Snow fell hard all the time, yet it required only 35 minutes to make 20 successive trips, with an average of 30 amperes. In the course of four hours the snow was nearly two inches deep, when the car was again started. The brushes alone were of no avail, and the snow plough had to be applied. The first journey was made in 2min. 20sec., but with the enormous expenditure of 80 amperes; each succeeding trip, however, took less time and energy, until it reached nearly to its normal value corresponding to clean rails. This would show that with proper appliances, and with cars rapidly succeeding each other, the track can be kept clear; but the accumulation of much snow in the first instance occasions a fearful demand of energy, and without plough and brushes the snow is compressed by the wheels and renders progress almost impossible.

Recent tests made by a commission on the Frankfurt-Offenbach Electric Tramway, which has been in constant operation for six years, gave the following results:—Two cars, one of which contained the motor, the other an ordinary car attached to it were taken over the line. The motor car weighed 4 tons, the ordinary car 2 tons, and 20 passengers 1½ tons, giving a total of 7½ tons. Measurements with an amperemeter were made every 5 seconds. The electromotive force varied between 240 and 300 volts. At starting the current used was 80 to 100 amperes, which fell to 40 in 10 seconds, and the mean current on the level road at 8 miles an hour fluctuated between 15 and 25 amperes. On a gradient of 2·85 per cent. 55 to 60 amperes were recorded, and the mean current over a distance of one mile occupying seven minutes was found to be 21·48 amperes, and this included four stoppages. The highest amount of energy recorded at any moment, when starting, was 21,700 watts.

Dr. Louis Bell, in an interesting Paper published a few months ago, gave the results of his experiments on the La Fayette Road (Ind.), from which I take the following instructive figures. Experimental runs were made on a level road with a car and passengers weighing together 8,200lbs.

Miles per hour.	Volts.	Amperes.	Electrical H.-P.
7·5	404	9·5	5·15
9·3	416	10·4	5·79
9·1	393	10·7	5·40
10·9	434	16·1	9·35
12·4	433	15·4	8·95

Another test on a gradient of 6·58 per cent. rise, one-tenth of a mile in length, gave the following results:—

Miles per hour.	Volts.	Amperes.	Electrical H.-P.
2·73	347	27·2	12·65
4·20	403	27·4	13·47
9·30	409	31·3	17·14
6·20	365	32·4	15·85

These results are remarkable when compared with those on the level road; considering the steep gradient, one would have expected a much larger consumption of energy at the necessarily low motor speed. On the other hand, the tractive force on the level road appears to be abnormally high at all speeds when the motor efficiency should be at its very best.

More recently Mr. O. T. Crosby published some interesting data concerning three American tramways which, like those of La Fayette, were worked by overhead conductors. The average expenditure of energy on one car on each of the following lines was:—

—	Watts.	Electrical H.-P.	Load.	Average speed.
Richmond	4,883	6·5	8,500	6 miles.
Cleveland	4,986	6·6	9,500	9 „
Scranton	5,587	7·4	9,500	5·7 „

The maximum gradients were given to be at Richmond 9 per cent.; at Cleveland "very slight;" and at Scranton 7 per cent., involving maximum expenditure of power of 25·6 horse-power, 15 horse-power, and 19·2 horse-power (electrical measurements on cars) respectively.

Dr. E. Hopkinson ascertained the mean tractive force on the Bessbrook-Newry Tramway, and he showed that it amounted to 28·9, 27·4, and 37·1lb. per ton of gross load hauled during three journeys. The increase in the third journey is due to the mean speed having been nearly doubled. The gradients are not severe in this case, but continuous in one direction.

From numerous sources at our disposal we find that the mean tractive force may be anything from 30 to 50lb. per ton, and that it is seldom, if ever, below 20lb. on level roads, excepting under very favourable circumstances.

All these figures point to the fact that the mechanical resistances on existing tramways are very great, and that even a slight reduction at a comparatively small cost would bring about a considerable saving in traction expenses. By reducing these resistances we not only save power with existing appliances, but by virtue of a smaller demand of tractive force we are enabled to utilise lighter motors, lighter gearing, lighter storage batteries, which, in their turn, again require less for their own propulsion until a practical limit is reached.

Assuming, *à priori*, high efficiency in electric motors and gearing, improvements as regards mechanical resistance on tramways may be looked for, and, I hope, attempted in the following points:—

1. Solid, well-fixed, parallel rails.

2. Perfect cylindrical wheels, with thin flanges, or some of them without flanges.

Digitized by Google

3. Clean rails. The grooves may be swept and watered several times a day by a vehicle especially fitted for this purpose.

4. Sufficient flexibility in axle boxes to allow of free movement in curves.

5. A reasonable number of graduations in the motive power, regulated by a switch.

6. Skilful driving, which should occasionally be proved by careful tests and power curves.

7. Automatic sand boxes on steep gradients where the natural adhesion is insufficient.

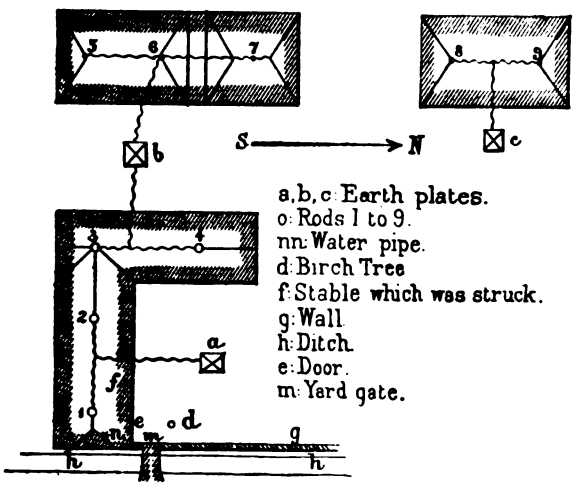
In conclusion, I will repeat that a frequent and judicious use of the ammeter on electric cars will amply repay you for the trouble; it will be the means of great improvements, in the same manner as the indicator diagram enabled us to study the nature of steam engines, and which has been the most direct means of effecting great economy in working.

A REMARKABLE FLASH OF LIGHTNING.*

BY W. KOHLRAUSCH.

On May 15th last I was asked to inspect a stable on the farm of Mr. C. Jagau, near Hanover. On May 8th it had been struck by lightning, which set it on fire and killed a horse which was in it, and this, although the building had four conductors, in the immediate neighbourhood of one of which the lightning struck.

The accompanying illustration shows the positions of the buildings and the conductors. To the east lies the yard, which seems to be quite unoccupied. To the south also there are no buildings within the distance of 100m. It was at the request of Mr. Rudolf Siemsen, who had erected the conductors, that I went to see the place. The iron rods are 4m. high and the 12-strand copper conductors have a cross section of 0·06in. The earth-plates



are 100 by 50 c.m.; those at *a* and *b* hang right under water in two wells; that at *c* is buried 1·5 m. deep in the ground. From the gilded tips of the rods down to the earth-plates, all joints were properly soldered. It might have been well to connect rods 2 and 3 along the roof, but with that exception no fault could be found with the arrangements. Those in the house had no idea that the stable had been struck until, shortly after, they saw smoke coming from the roof, and found that some loose hay lying in the loft was burning, which was easily extinguished; but it was found that a horse was lying dead just within the door. Distinct traces of the flash, in the form of numerous small splinterings, could be seen on the first two beams going to the north-west, under the ceiling of the stable behind the door *e*. Wood was splintered both on the inner and outer sides of the door itself, and here and there its nails and bars were melted at the ends and angles. The yard gate was also splintered. Finally, on the birch-tree *d*, at about 1·7m. from the ground, we found two burns, which were undoubtedly fresh, and which had gone through the bark to the better conducting interior of the tree. The most careful search has not brought to light any other traces of the lightning's course. We took down the conductor 1, but even with a magnifying glass could find no traces of its being touched by lightning. Rod 2 we examined through a telescope with the same result. The common conductor of rods 1 and 2 goes to earth at the well *a*. The water was about 1·5m. below the ground. The well is built in sandstone, and is about 3·5m. deep. The earth-plate *a* was quite under water.

Earths *a*, *b*, *c* were 10 ohms, 11 ohms, and 32 ohms respectively. There is thus nothing much to be said against the arrangement of the conductors. It would have been better had the resistances of the earths been smaller, and had rods 2 and 3 been connected; but I think one can hardly say that the buildings were insufficiently protected, and I can find no definite reason for the fact that the lightning injured them; and, moreover, injured them at a spot certainly not beyond the commonly supposed protective distance of the rod, and which was nowhere more than 5m. from either end of the rod. In this region the ironstone, which lies generally about a metre below the surface, in various sized beds, has a great deal to do with determining the course of a flash of lightning; but, on digging in the stable, near the birch, and round the neighbourhood where the lightning struck, we came to the water-level at 1·25m. down, but found no ironstone. The nearest we found was a small bed in the field, towards the east and about 25m. from the stable. The field lies about 0·8m., and the water in the ditch *h* about 1·3m. lower than the yard. In the stable or beneath it, was no amount of metal worth mentioning. No farm implements were kept there; the stable was empty, save for the horse, which happened to have been put there temporarily.

The following explanation is possible:—The lightning struck the highest point in the neighbourhood, the birch *d*, passed through the twigs at *n*, which touched the roof of the building, and also through the tree, coming out lower down the tree, from whence it injured the yard gate *m*. All visible traces left by the flash fit in with this theory, for all the injuries to the building itself are just under the twigs *n*.

* From the *Elektrotechnische Zeitschrift*.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, May 9th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Colour Vision and Colour Blindness." By R. BRUDENELL CARTER, F.R.C.S.

TUESDAY, May 13th.

INSTITUTE OF MARINE ENGINEERS.

7:30 p.m. Paper to be read: "Corrosion of Iron and Steel. By D. PHILLIPS.

INSTITUTION OF CIVIL ENGINEERS.

8 .m. Ordinary Meeting. Paper to be further discussed: "The Screw-Propeller." By SYD. W. BARNABY, M.Inst.C.E. Paper to be read, time permitting: "The Keswick Water-Power Electric Light Station." By W. P. J. FAWCUS and E. W. COWAN, Assoc.MM. Inst. C.E.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. "The Use of Alloys in Art Metal-Work." By Prof. W. C. ROBERTS-AUSTEN, F.R.S.

WEDNESDAY, May 14th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Lecture: "Prof. Elihu Thomson's Electro-magnetic Induction Experiments." By Dr. J. A. FLEMING, M.A.

ROYAL SOCIETY.

9 p.m. Conversazione.

THURSDAY, May 15th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Flame and Explosives." By Prof. DEWAR, F.R.S.

CHEMICAL SOCIETY.

8 p.m. Papers to be read: "On Diethylphosphorous Acid." By Prof. THORPE, F.R.S., and Mr. BARKER NORTH; "The Ten Isomeric Dichloronaphthalenes," and "The Action of Chlorine on Naphthalene and Naphthalene Derivatives," by Prof. ARMSTRONG and Mr. W. P. WYNNE; "A Third Naphthaquinone," by Prof. MELDOLA and Mr. FRANK HUGHES.

FRIDAY, May 16th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: "On Huygen's Gearing in Illustration of Electric Induction." By Lord RAYLEIGH, F.R.S. "Dr. R. König's Researches on the Physical Basis of Music." By Prof. SILVANUS THOMPSON, D.Sc.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Photographic Image." By Professor RAPHAEL MELDOLA, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and to be crossed* "*Coutts and Co.*"

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The Directory was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

EFFICIENCY OF GLOW LAMPS.

Among the many subjects which the progress of electrical engineering has brought into prominence of late years is the question of the efficiency of incandescent lamps, the importance of which is sufficient to merit fuller attention than it has yet received. Although; no doubt, a very large number of investigations have been made, the whole question is not nearly so clearly understood as is, for example, the theory of dynamo design. This is largely due to the fact that experiments on lamps, to be of any great practical value, must not only be spread over a long period of time, but must also be made on a large number of lamps so as to secure good average results. Other subjects can be more or less satisfactorily dealt with by individual experiments; but the only way this question can be properly attacked is by means of the method of averages. As a matter of fact, the greater number of experiments hitherto performed have been rather of an individual than of a collective nature, and are thus open to objection. It is scarcely possible to expect companies to devote a large amount of trouble and time to a question of this kind; but it is a great and promising field for a private investigator who is fortunate enough to have at his disposal the time and means needed to

Digitized by Google

carry out the work. If such a one were to run a large number of lamps of the same type at various voltages, keeping careful time-records of the individual life and candle-power of the same during the whole time that the lamps lasted, he would secure a large amount of valuable information, which is much needed and which would be eagerly welcomed by electrical firms. The causes of individual variations is, again, a subject of which little is publicly known, but which would richly repay separate investigation. Among such causes are the state of the vacuum, the nature of the surface and the form of the filament, all of which considerably influence the radiation coefficient; not to mention more obscure points, such as the conduction of heat down the terminal wires.

But apart from the difficulty which arises from the existence of individual peculiarities, there are others arising from the nature of the investigation itself. The very definition of lamp efficiency is obscure, since the circumstances under which efficiency is to be measured are by no means generally agreed upon. No doubt the most scientific way to measure the efficiency would be to take the ratio of the light energy given off to the electrical energy supplied; but this is quite impracticable, owing to the impossibility of measuring the intensities of the different component rays in the emitted light and afterwards summing the whole. What is usually taken to indicate the efficiency is the number of watts required to produce each candle-power of light in the lamp; and, as this is practically what is required to be known, we cannot at present do better than continue the use of the term in this sense. However, after the adoption of this as the meaning of the term "efficiency of a lamp," we are met by other difficulties, for it is well known to be possible to get almost any efficiency, even as high as one-fifth of a watt per candle, provided shortening the life of the lamp is no consideration. The efficiency of a lamp, instead of being constant, may be almost anything, depending on the life. Without a vast amount of preliminary investigation it is impossible to test lamps with currents such as they would stand on the average for equal intervals of time; so that we may say that it is impracticable to test lamps under the conditions of equal life. The alternative, recently suggested in our correspondence columns, of testing the life of lamps under conditions of constant efficiency is more practicable and worthy of attention, although open to some objections. While, however, it is impossible to speak generally of the maximum efficiency of any particular lamp, it is quite possible to speak of the maximum efficiency of a particular type of lamp when we are given the cost of power and lamps as well as the average life. Curiously enough, the maximum efficiency in every case arises when the cost of lamp renewals is about 15 per cent. of the total operating expenses of the plant. It should be carefully noted that in this case it is not the goodness of the lamp which altogether determines the efficiency under these conditions, for local questions are also of great importance.

The foregoing considerations sufficiently account for the usual plan of testing the lamp efficiency at the voltage recommended by the makers, and of making separate determinations of candle-power and life at that voltage. Perhaps the most complete set of tests made, since the celebrated ones of the Franklin Institute, are some by Mr. W. L. PUFFER, which recently appeared in the *Electrical Engineer* of New York. Although very complete, and made on several types of lamp, they are not in any way average results, but refer solely to the individual lamps employed by his pupils in the tests. The lamps experimented on were of fairly recent manufacture and bought in the open market. The standard used was a carefully adjusted Methven screen, and by means of an ingenious holder each lamp could be turned or raised to any desired degree. Five characteristic curves are given for each lamp, and, by an admirable method of plotting, all possible information is given in a way so that the capabilities and peculiarities of each lamp can be seen at a glance. The results are of interest as showing how near the rated value of a lamp is to its true value, and also how largely the efficiency of good lamps may vary even when of the same type. Although in about half the cases the mean horizontal candle-power comes out above the rated value, in every case the mean spherical candle-power is considerably below, and only represents about 90 per cent. of the rated value. The efficiencies vary largely, from 3 to 6 watts per candle; and although from the absence of any data with regard to the life of the various lamps it is impossible to compare the results, it is interesting to notice that such large variations are possible with lamps worked at rated voltage, and this fact alone shows that the manufacturer of glow lamps is far from equalling the dynamo maker in being able to turn out a large number of articles which are all practically identical. Mr. PUFFER points out the importance of such experiments in connection with the rated power of lamps. The fact that the mean horizontal and mean spherical candle-power may differ so greatly not only shows up another difficulty in measurement, but also renders it desirable to define more explicitly than has hitherto been done the exact meaning of the candle-power of a lamp. Electrical progress has been already so much injured by lawsuits that no precaution should be neglected by means of which future litigation may be lessened. It is to be hoped that some capable investigator will take up the entire question, so as to procure a more complete set of experimental data than any we are in possession of at the present time.

THE BOARD OF TRADE AND ELECTRIC LIGHTING COMPANIES.

The President of the Board of Trade, Sir Michael Hicks-Beach, M.P., received on Friday last a deputation from electric lighting companies respecting the clause in the Model Provisional Order giving local authorities the power of absolute transfer of Provisional Orders under the Electric Lighting Acts.

Sir J. PULESTON, M.P., in introducing the deputation, said that they came there to the Board of Trade because they were sure that the Board desired to facilitate rather than to retard the progress of electric lighting. He might say at once that he had no personal interest in this matter, but he was inclined to take a general interest in it since the first Parliamentary Committee of 1882, of which he was a member, and he recollected that the question of delegation was one on which they stated their views very strongly. Under this Clause 60 of the Model Provisional Order practically the local authorities would be able, if they felt so disposed, to sit upon the Provisional Order, for the great interest local authorities invariably had in gas companies would considerably influence them in the direction. The Act of 1888 provided for the longer tenure of 42 years, but he considered if the powers proposed by this transfer clause were conceded to local authorities, they would be in a position to reduce the time again to 21 years.

Mr. J. FLETCHER MOULTON, Q.C., said that Sir Michael would probably remember the Select Committee of 1882 before which the Electric Lighting Bill came, and the whole question of the transferring of Provisional Orders or Licences was considered very carefully; and he thought that the dominant feeling in the Committee was that if their rights were granted by Provisional Orders or Licences they should not be in the nature of concessions in which traffic could take place; that the power of supplying the electric light in a district was consistent with public duty, and was not a matter which should be handed from one person to another without the direct control of Parliament. He remembered that it was most distinctly stated by the representative of the Board of Trade, and he could certainly say it came before the whole of the Committee, that local authorities, if they came forward to ask for power to distribute electricity, their intentions must be *bonâ fide*, there must be no "dog in the manger" policy; and he might also say, it should be their intention to immediately put it into effect. He did not for one moment mean to say that the views of the local authority should be disregarded; but it was never intended that the local authority should necessarily stop a company from supplying the public with the electric light, and, further, it was not intended that the local authority should have powers if they did

Digitized by Google

not mean to do the work. In 1888 another Committee was appointed by Parliament to consider the question of electric lighting, as the thing had practically broken down because the Electric Lighting Act allowed so short a period as 21 years in which the Company would have to establish its works, get customers, make its profits, and provide for depreciation. 21 years was too short, and the Act of 1888 dealing with this put down 42, which he thought a very reasonable number of years; but, at the same time, a clause was put in giving greater statutory weight to the position of the local authority. Otherwise he thought the Act of 1882 practically remained unchanged. Now, last year, he believed for the first time, at the application of one local authority, a clause was put in the Order giving that local authority the power of transfer. That was, he believed, in the case of the Swansea Electric Lighting. The question of this transfer clause being put into the Orders has been before the companies, and he thought the Board of Trade at the commencement of the year rather favoured its not being inserted; but there had been a discussion on the subject with the municipal authorities, and he understood it was going to be inserted in all Provisional Orders granted to local authorities. In his opinion, this transfer clause was contrary to the principal Act, which overrides all Provisional Orders. It was not within the power of a Provisional Order that it should be allowed to be transferred, without going to Parliament, from a local authority to a company, and he submitted that it would be very detrimental to the interest of the public if this clause were inserted.

The PRESIDENT: The Act already enables the Board of Trade to sanction transfers.

Mr. MOULTON said that this was quite different to the proposed clause; for whereas one provided for the transfer of certain portions of the Order, the other gave the power of bodily transferring the whole of the Provisional Order. Mr. Moulton then read Clause 4, which he said provided that no Provisional Order could authorise the supply of electricity unless notice had been given of such Provisional Order. But under the new clause it was different. The local authority might give the notice, and might obtain the Order. The local authority would be able to transfer the Order to a Company, and that Provisional Order would authorise that Company to distribute electricity, although the Company had not given any notice. If this was to be the case, a body of middlemen would be created, and they would decide—not the Board of Trade, not Parliament—who were to be the undertakers. Mr. Moulton said, of course the granting of a Provisional Order to local authorities was a step which Parliament regarded with very great favour; but he submitted that it was intended that powers for distributing electricity should not get into the hands of any company without this notice to the public, and that the Provisional Order was intended to mention the persons who were to be the people to have the direct supply.

The PRESIDENT stated that, so far as the Board of Trade were concerned, companies would get as much protection as before, but he supposed they were afraid of losing the protection of Parliament.

Mr. MOULTON said they would lose the protection of Parliament, and he also believed in a measure they would lose the protection of the Board of Trade. They had heard of grave abuses by municipal corporations in other countries, but he hoped they would not have them in his country; still he submitted it was necessary to consider this. He submitted that the clause not only went beyond what was meant by the Act, but it was organising a mode of dealings in concessions.

Mr. HENRY KIMBER, M.P., referring to the fact that the President had stated that they had the power of revoking the Order after the lapse of two years when nothing was done under same, said that in the case of Brighton the Corporation had had the Order for seven years, and had only just recently intimated the intention of undertaking the responsibilities of the Order. He was quite sure that in some cases if the public had an opportunity of coming to the Board of Trade the position of local authorities who had obtained powers under the Electric Lighting Act would be very different.

The PRESIDENT said that the local authorities were the elected representatives of the public. He did not look upon local authorities in the same light as private companies.

Mr. B. R. W. WILLIAMS said that Sir Michael would probably remember that last year he had an interview with him (Sir Michael), and he pointed out that in 1883 a great number of Provisional Orders were granted to Corporations and also to private companies, and whereas in every case of the latter the Orders had been revoked, not one of the Orders of local authorities was revoked. He (Mr. Williams) pointed out the injustice of this, and in reply Sir Michael said that he looked upon local authorities in a totally different light to supply companies.

The PRESIDENT: You are carrying my words rather farther than I intended. I did not say I would not revoke any Order of local authorities.

Sir JOHN PULESTON remarked that the real point was, they were desirous of promoting the science of electric lighting, and did not wish to see its progress impeded.

The PRESIDENT: I do not think it is the business of the Board of Trade to force the electric light on any town.

Sir J. PULESTON: No, but to facilitate it.

The PRESIDENT. Ah! the two words have very much the same meaning in this sense. If the local authority used the powers given them to keep the electric light out of its town I should, of course, not allow that.

Mr. KIMBER: Then I hope you will hear anybody who can adduce instances of these cases.

The PRESIDENT: Yes, certainly.

Mr. KIMBER: But you say, Sir, that you cannot have the public here.

The PRESIDENT: I say it is not within my right to interfere with the public, because they have their own elected representatives.

Mr. MOULTON was proceeding to refer the question of spending the ratepayers' money, when

The PRESIDENT (interrupting) said: The question of obtaining the money is another point. The argument laid before me is that the local authority will not spend more; they will do nothing directly or indirectly in electric lighting. I think that you had better submit to me in writing your objections to this clause. Mr. Moulton has stated them very ably, and I should like to have them before me. I should particularly like to have your views as to the question of the terms. It could be argued that it is one thing for local authorities to do the work, to establish works of their own, and then let them from time to time; but it is another thing to give over the concession for 21 years.

The deputation then thanked the President of the Board of Trade, and withdrew.

CENTRAL LONDON RAILWAY BILL.

HOUSE OF COMMONS.—FRIDAY, May 2nd.

Mr. PEMBER, Q.C., having stated that an arrangement had been come to with the Gas Light and Coke Company, by which further opposition on their part would be obviated, Mr. Rigg proceeded to call evidence on behalf of the London, Chatham and Dover Company in opposition to the Bill.

Mr. FORBES, Chairman of the Company, said in his opinion the line must turn out a financial failure, and at the same time the Central London Company would be occupying ground which some one else might want for the construction of an ordinary underground railway worked by steam. His Company would be prepared to construct such a line, supposing there were the slightest probability of their obtaining the consent of the frontages.

Mr. BINNIE, Engineer-in-Chief to the County Council, and Mr. S. HARRISON, Chairman of the Parliamentary Committee, gave evidence as to the protection which would be required to the sewers; and Sir JOSEPH BAZALGETTE said he considered that the scheme, if carried out, would greatly interfere with the sewers.

MONDAY, May 5th.

Mr. LITTLER, Q.C., addressed the Committee on behalf of the Corporation of the City of London in opposition to the scheme. He said his clients were only too anxious to see any increased means of locomotion adopted which would tend to the comfort and convenience of the travelling public; but they objected to the ground being occupied by a scheme which might or might not be a success. In the present state of engineering experience of the means of locomotion proposed, the Committee would not be justified in authorising such a scheme as the present for some year or two—at any rate, until experts had been to America and reported exhaustively upon the working of the electrical lines there. Supposing this line turned out a failure, there would be a tube left in the ground that would be absolutely useless for any purpose whatever.

Mr. BELL, on behalf of the Metropolitan Railway Company, examined by Mr. Littler, said: Such stress had been laid upon the success of the system of working by electricity in America, that he had been there to see it in actual working, and he found nothing but tramways with only one car working at a time. On the Manhattan Railway, which was 25ft. above the ground, experiments had been made with electrical traction at a cost of $100,000, which turned out a failure, and he had seen the electrical engine lying on the rails rusting and useless.

To Mr. Freeman: If any further development of underground traffic were called for within the circle of the metropolis, his Company ought to have the first chance. He would admit that this route contained the plum of the traffic, and the Metropolitan would be very glad to lay down a line along it, if there were the least likelihood of getting the consent of the frontagers. For the last three years a system of working by electricity on the Underground Railway had been under consideration, but the expense attending such a change would have been very large, and at present they were not satisfied that any system of working that had been before them would be satisfactory. When in America he had not seen two cars containing 96 passengers working on a gradient of 1 in 8 by the Thomson-Houston system. If it were the case such a thing could not have been done by an ordinary locomotive.

After some further evidence, Mr. LITTLER addressed the Committee on behalf of the Metropolitan Railway Company in opposition to the Bill, after which the Committee adjourned.

TUESDAY, May 6th

Mr. PEMBER, Q.C., replied on behalf of the promoters. He said there were originally 37 petitions against the Bill, but now he had only some 19 or 20 petitions to deal with. There were six points which had been urged against the Bill: (1) Engineering risks; (2) Injury to Oxford-street tradesmen; (3) The question of subsoil; (4) The question of the feasibility of electrical traction, and the working expenses incidental to the application of electrical traction; (5) The chances of traffic if the line were once made and put into operation; and lastly, that precious plea for postponement, which had been put forward on behalf of nearly every one of the opponents. With regard to the first point, they had the experience of the construction of the Metropolitan and District Railways, and other railways. With regard to damage caused during construction, it had been stated by Sir Benjamin Baker and others that the total amount of damage caused during the construction of the City and Southwark Railway would be covered by a sum of £10,000. It was proposed to construct the line throughout in the London clay; and in 57 borings which had been made in the four miles of line, they had found the London clay in every case, and even if it should turn out that

Digitized by Google

there was a pocket of sand or gravel, they would be able to minimise any danger by working with shields and the compressed air system. The learned counsel contended that some underground scheme was absolutely necessary; and he asked the Committee, after hearing the evidence which had been given by such eminent engineers as Sir John Fowler, Sir Benjamin Baker, and Mr. Greathead, to sanction an electric scheme of the kind proposed as being preferable to an ordinary railway worked by steam. In order to pay a fair interest upon working expenses it had been calculated that they would require to carry 28,000,000 passengers; and remembering that the Metropolitan and the Metropolitan District carried 117,000,000, it was not a very violent assumption to expect that the proposed line would carry one-fourth or less than one-fourth of that number. On the proposed line they only looked for an average fare of 2d., as against the present average omnibus fare of 1·66d., and that, it must be remembered, was earned from passengers whose average journey was only a mile and a-half. When judged by the ordinary standard of Parliamentary proof by evidence in favour of such measures as this, the probabilities of ultimate success were unusually high.

The Committee then deliberated in private for some time; and on the re-admission of the parties,

The CHAIRMAN (Mr. Walter James) gave the following decision:—The Committee find that the preamble of the Bill has been proved, subject to the promoters satisfying them upon the following points:—They consider that a proviso should be inserted at the end of Clause 35 of the Bill similar to that which was inserted in the Midland Railway (Additional Powers) Act, 1881, providing that nothing shall relieve the Company from liability to pay compensation under Section 68 of the Lands Clauses Consolidation Act. The Committee also consider that stringent clauses should be inserted affording every opportunity to the engineers of the Corporation of the City and of the County Council during the progress of those works for inspecting them, lest any possible damage should be done to the sewers, mains, or other public works under the streets, and that the owners of property and all the local bodies should have full opportunity of watching their own interests. The Committee also consider that the margin in the financial proposal of the Company is somewhat too large, and that is a point they will have to consider in connection with the estimated capital of the Company. The remaining point is, that they consider that, until the City and Southwark Subway has been opened, and has been used by the travelling public for a certain time, no prospectus of the Central London Railway should be issued, and no capital should be raised.

Mr. SAUNDERS, Q.C., on behalf of the promoters, gave an undertaking to bring up clauses carrying out the decision of the Committee, and to supply all the opponents with copies.

The Committee then adjourned until next Tuesday for the discussion of clauses.

THE RAILWAY RATES INQUIRY.

The Board of Trade inquiry as to the tables for the classification of merchandise prepared by the railway companies in compliance with the provisions of the Railway and Canal Traffic Act of 1888, has been continued during the present week.

Upon the article "wire, cotton-covered, in casks, hampers, cases and canvas-covered coils,"

Mr. TROTTER, for the Electrical Section of the Chamber of Commerce, said there seemed to be some misconception as to the nature of this article and its value. It was objected by the railway companies that it was used for the same apparatus, and was equally if not more valuable than gutta-percha-covered wire, which was in Class 4, and to which the traders had no objection. But cotton-covered wire was essentially a raw material, as far as dynamo makers and manufacturers of electrical machinery and apparatus were concerned. It was a heavy article, and of a value only about 23 to 25 per cent. more than that of copper wire. It was not liable to damage, and he had information from various manufacturers saying that 1 per cent. covered all the damage they experienced. The value of the gutta-percha wire varied from £200 to £300 per ton, and it was considerably liable to damage. A very small amount of damage to gutta-percha wire would simply ruin it. He did not press for any alteration in this respect; but cotton cooper wire went in canvas-covered coils and casks, and frequently travelled in wooden drums, which were sent from the coverer to the manufacturer, and then it was practically unable to be injured It was easily loaded in quantities. It was heavy, and was well packed, and it went directly from the wire coverer to the manufacturers of electrical apparatus.

Lord BALFOUR of BURLEIGH remarked that Mr. Trotter was under a misapprehension as to the class in which these articles now appeared. The railway companies said that "the second-class entry in the clearing-house classification to which presumably the objectors allude does not refer to wire for telegraph or electrical purposes, but for millinery and other similar purposes.' After that explanation would the traders be satisfied with the clearing-house classification?

Mr. TROTTER said he had noticed the observation of the railway companies, but he did not see any further entry in the clearing-house classification than copper-covered wire for telegraph or electrical purposes. He was not aware that they intended wire used for millinery and similar purposes. He had used many tons of it.

Mr. WILKINSON (Great Western), in replying to a question by the Court, stated that these goods at the present time were in the third class, under the entry "wire, copper, or brass." The railway companies thought that one class higher was reasonable for this article. They were themselves very large consumers of it, and were fully acquainted with its value, which was very great. Ordinary copper wire was worth £120 per ton; this was worth £200. The railway companies were prepared to leave the matter in this way. Common wire was in Class 3, and one class more was a reasonable thing for wire covered in this way. Their present powers were, of course, the highest they had. It was a bulky article, and was liable to damage. If a cask or case got wet, the company would be called upon to pay.

Lord BALFOUR OF BURLEIGH: Is this article all copper wire?

Mr. TROTTER: Entirely copper.

Lord BALFOUR OF BURLEIGH: Then it ought to be so described.

Mr. TROTTER said the traders were quite prepared to describe it in that way, but there were some quantities of German silver and other wire used. They were quite prepared to distinguish the copper wire. The increase in value for covering the wire was about £18 per ton; the bulk was not more considerable—the difference was unmeasurable. Cotton-covered copper wire was worth about £72 per ton at the present moment.

LEGAL INTELLIGENCE.

Chamberlain and Another v. The Cadogan Electric Light Company.

In the Queen's Bench Division, last week, before Baron Huddleston and Mr. Justice Grantham, this case came on for hearing. Mr. Hugo Young appeared for the plaintiffs, and Mr. Ruegg represented the defendant Company.

This was an appeal on the part of the defendants from the decision of the County Court judge at Birmingham, particulars of which will be found in *The Electrician* of March 14, p. 482.

Mr. RUEGG said that the defendants did not now appeal as to the judgment on the counter-claim, and only contested the County Court judge's decision as to the claim. In substance the judge found in favour of the defendants, on the fact that the meters supplied to them by the plaintiffs were not reasonably adapted for the purpose of registering electricity; but he held that in law, upon the correspondence, there was no express warranty, and that, under the circumstances of the case, the usual implied warranty that the manufacturer who manufactured an article, and supplied it for a given purpose, warranted that it was reasonably fit for that purpose, did not apply. His (Mr. Ruegg's) contention was that the County Court judge was wrong on both grounds. He said there was, in the correspondence in the case, an express warranty that the meters were fit for the purpose for which they were supplied, and that there was the usual implied warranty which attached to manufacturers who supplied an article, knowing for what purpose it was to be used.

Mr. HUGO YOUNG, for the plaintiff, in support of the decision of the learned judge at Birmingham, said his Honour had found, as a fact, that a meter to measure electricity was a new article in the trade; and it was known to all electricians that, up to the present time, there was no such thing known as a perfect meter to do this work. Therefore, what the judge had found was, that the circular issued by the plaintiffs was merely a trade circular describing a general class of article, and intended to convey what the meters might be expected to do under proper circumstances and conditions. But the judge had said that the circulars were by no means a warranty of what the meters would do on all occasions.

Baron HUDDLESTON, in giving judgment, said the real point which the Court had to consider was whether the County Court judge was right in point of law in saying he could not connect the correspondence between the parties in March with the sale at a subsequent date. His Honour seemed to be of opinion if he could do that he would have found a verdict against the plaintiffs. He thought the correspondence could be imported into the contract, and that being so there was no doubt that there was an express warranty, because plaintiffs, in one of their letters in answer to defendants, said, "If you are in want of a reliable meter we can assure you you need not look any further, as you will find ours both reliable and practical." Judgment would therefore be entered for the defendants, and the appeal allowed with costs.—Mr. Justice Grantham concurred.—Leave to appeal was refused.

Re the International Cable Company.

A petition presented by Mr. Bolton for the winding up of this Company was heard on Saturday last before Mr. Justice Stirling, in the Chancery Division of the High Court of Justice.

Mr. Buckley, Q.C. (with him Mr. John Chester), for the Company, asked for leave to use further evidence on the petition which had just been received from Paris from Mr. Dijon; but

Mr Hastings, Q.C. (with him Mr. G. Woods), for the petitioner, objected to its reception on the ground that the evidence had been filed after the petition was opened on the previous Saturday.

His Lordship declined to allow the evidence to be used.

Mr. HASTINGS said this was a petition by a contributory, asking that the Company might be wound up, on the ground that the substratum of the Company had gone. The Company was formed in December, 1885, with a nominal capital of £1,000,000 in £10 shares, to lay a cable between Portugal and America, but up to the present it had done nothing but lay the shore end at one place, and to obtain from the Government a contract for laying a cable between Halifax and Bermuda, which had been handed over to the Halifax and Bermuda Company, in which this Company had a large interest. In November, 1886, the Company issued its prospectus. Among other applicants for shares was the petitioner, who now held 1,000

Digitized by Google

shares, upon which he had paid £1,000. Nothing like the requisite number of shares had been applied for which the Directors said were necessary to commence operations with. After the allotment in December, 1886, an extension of the Portuguese Government's concession was obtained till June 30, 1888, and it was again extended till June 30, 1889; and the petitioner alleged that it was impossible to obtain any further renewal. The Company did not dispute that the concession had lapsed, but their case, according to the evidence, was that they had hopes of getting it renewed and extended. As the real thing which the shareholders had been invited to join the Company to work, namely, the laying of a cable under a particular concession, could not be carried out, it was perfectly clear that the petitioner was entitled to a winding-up order.

TUESDAY, May 6th.

After a further statement by Mr. GROSVENOR WOODS, who appeared with Mr. GRAHAM HASTINGS, Q.C., for the petitioner.

Mr. WARRINGTON, on behalf of seven shareholders holding 3,410 shares, representing £34,100, supported the petition.

Mr. BUCKLEY, Q.C., and Mr. CHESTER appeared for the Company, and for the holders of 5,075 shares, and opposed the petition. Mr. Buckley said the total number of shares issued was 25,914, upon which £69,049 had been paid, and submitted that the Court would not, on behalf of one shareholder, make a winding-up order when the large majority were in favour of going on. He denied altogether that the substratum of the Company had gone, and referred to Clauses *p* and *q* in the memorandum, which gave the Company power to form new companies and take shares therein, and to the fact that the International Company had formed the Halifax and Bermuda Company, and were largely interested in its success; and, as the British Government had granted a concession to the Company, under which they would pay a subsidy of £8,100 a year, it could not be said that the Company had not commenced business. He also denied that the Portuguese concession had lapsed altogether, no decree having been passed putting an end to it, and the Directors had every hope that it would be renewed.

Mr. CHESTER having followed, and cited several authorities bearing on the question of whether the substratum of the Company could be said to have gone,

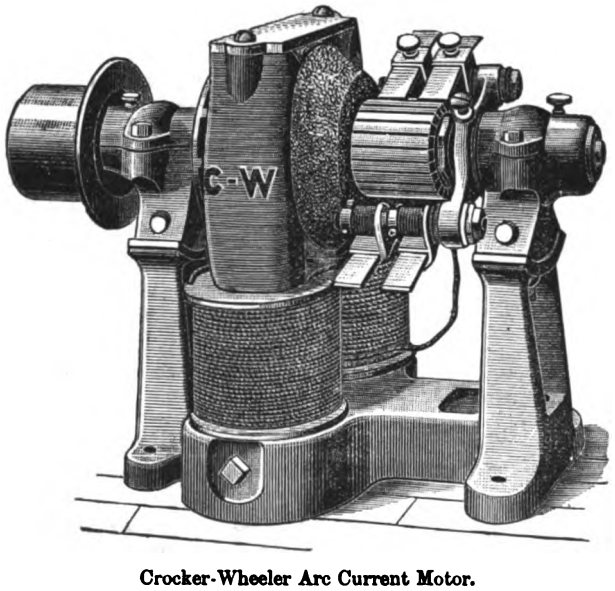
Mr. BAINES, on behalf of 12 shareholders holding 1,178 shares, in respect of which £11,490 had been paid, and for three creditors whose debts amounted to £70, also resisted the petition.

Mr. HASTINGS having replied at some length,

Mr. JUSTICE STIRLING said he would give judgment in a day or two.

THE CROCKER-WHEELER ARC CURRENT MOTOR.

Mr. F. B. Crocker and Mr. S. S. Wheeler, says the *Electrical World*, have produced a self-regulating constant-current motor that overcomes many previously existing obstacles. Heretofore at-



Crocker-Wheeler Arc Current Motor.

tempts have been made to regulate such motors by changing the magnetic strength of the field; but this arrangement is likely to cause the serious defect of sparking at the commutator, and does not admit of instantaneous regulation. This latter is apparent, for an appreciable time must elapse before the change of strength of the magnetism can exert itself, and the machine will "race" before the governor can control it. In the motor under consideration these difficulties are overcome, as the regulation is effected by moving the armature shaft on its bearings in and out of the field, thus instantly increasing or diminishing, proportionate to the load, the amount of torque. By this arrangement is avoided the shifting of the line of commutation, and the result is the entire absence of sparking. The moving of the armature shaft, which is controlled by a mechanical device, also distributes evenly the wear on both the bearings and the commutator. The electrical conditions of the machine are thus undisturbed, so that a continuous current is maintained throughout the circuit, and the armature may be at rest for any length of time, with the full strength of the current flowing through it, and yet sustain no injury. In running pumps and elevators this property is particularly advantageous, and it is one of the essentials in which this motor differs from the constant potential motor, which is destroyed if the full pressure of the current meets the armature for even a short period while the armature is at rest.

The speed of the motor will not change with a varying current, even though the range be from 10 to 5 amperes. The ½ horse-power machine shows a difference of potential of less than 50 volts on a 10-ampere circuit, and the 1 horse-power of less than 100 volts. In small motors the regulation is effected by hand, and in the motors of ½ horse-power and upward by automatic control.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 18, 1890.

A New Vacuum Pump for Incandescent Lamps.—A novel vacuum pump for exhausting incandescent lamps has put in an appearance, suddenly coming to the front after a couple of years of quiet experimenting. Instead of being a mercury pump, it is a modification of the cylinder air pump. The radical improvement, however, consists in the fact that the pump is a compound one, two of the pump cylinders not only doing their share of exhaustion, but keeping a vacuum jacket around the third cylinder. As the difference in pressure between the outside and the inside of this last cylinder becomes very small indeed, there is almost no tendency to leakage in the joints, and a vacuum can be obtained comparing well with that reached by good mercury pumps, and as the pump cylinders are large, the exhaustion goes on more rapidly. During a recent test at Boston a large bank of lamps was completely exhausted, and the current turned on in 23 seconds from the time the pump was started.

A Motor without Field Magnets.—A motor has recently been patented here which is worthy of some study from those persons who are disposed to neglect the magnetic effect of the armature in dynamo-electric machinery. The motor in question has three armatures, and no field-magnets at all. The brushes of these armatures are symmetrically disposed, each pair being distant from each other 60 degrees, with a result that the poles formed in the three armatures control each other so as to cause continuous rotation. An experimental machine using three armatures of the size employed in 6 horse-power motors has been completed, and runs well.

The Edison and Thomson-Houston Companies.—The alleged combination between the Thomson-Houston and Edison interests has proved, as I suggested in a recent letter, to be no more than a quiet agreement not to cut each other's throats in the matter of prices quite as much as they have been heretofore doing. It is no easy matter to unite two gigantic corporations, and their relations can never be the most harmonious; but there has been such deadly competition in electrical matters recently that the companies are glad enough to call a truce without entering into any formal combination.

NEW YORK, *April* 24, 1890.

The New York Street Lighting.—There is mingled indignation and amusement among electric light companies in this city at the threat made by the Gas Commission to abandon electric light and go back to an attempt at street lighting with gas. Owing to the great trouble in getting proper subway accommodations, and the increased expense of operating where subway construction is used, the electric lighting companies, when the propositions were made for the next year's service, raised their price. Last year the contracts were let at a price of about 35 cents per lamp per night. This year, however, all bids made on the city lighting ranged in the vicinity of 40 cents, 39 cents being perhaps a fair average. At the present

Digitized by Google

price of subways there is very little money in lighting even at this latter figure, and as the companies do not care to light the streets for glory, it is not expected that much lower bids will be obtained. The Gas Commission, however, waxed exceedingly wroth when the bids were opened, and raised a howl of corruption and combination, which has up to the present produced little or no effect. One thing is very certain. The public will not tolerate dark streets after some years of excellent lighting by electricity. As to the electric light companies, up to the present they are minding their business and waiting further developments, with every probability of getting ultimately their own terms.

High-Speed Electric Traction.—High speed electric traction seems to be one of the probabilities of the near future. The Weems Electric Railway Company is transferring the scene of its experiments to a point near New York, and is about to lay down four or five miles of experimental track.[1] This is the system which reached a speed of over two miles a minute in some of the earlier experiments made near Baltimore; and as the engineering and operation of the problem are in skilful hands, and the Company is well backed, it seems likely that the feasibility of extreme high speed will be demonstrated in the near future. What the final results will be, of course, no one can tell at this time; but there is every prospect that we shall be treated to some striking experiments. A rather extraordinary project for reaching the same end is being pushed in Boston by the Portelectric Company, and several miles of experimental track are being laid down there. It will be remembered that this system involves what is almost a continuous solenoid the entire length of the track; and although no experiments on a practical scale have as yet been made, the Company is making a great deal of talk about what it proposes to do; and electricians, most of whom have viewed the project with rather sceptical eyes, are waiting eagerly to see something done. The possibility of reaching enormously high speeds by the use of electricity no one doubts; and for transporting parcels, mails and the like, such systems would be immensely useful; but whether the public would take kindly to speeds approximating that of a mortar shell, remains to be seen. However, 30 miles an hour was denounced as desperately dangerous and well-nigh impossible in the early days of steam railroading, so that it is not impossible that a few years hence we may be as thoroughly reconciled to three miles a minute as we are now to one.

The Westinghouse Electric Railway Company.—It transpires that the new Westinghouse Electric Railroad Company which is about to be formed will not use the alternating system, but, instead, a direct-current system with overhead trolley.

Combination of the Brush and Julien Storage Battery Interests.—A report has come to hand of an approaching combination of the Brush and Julien Storage Battery interests with the Daft Motor system. This would look as if there was to be an attempt to develope storage battery traction.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

May 7, 1890.

An important question is at the present moment occupying the attention of our municipal authorities, viz., how best to light the big shop known as La Belle Jardinière, which is situated in the Rue du Pont-Neuf, 400 metres away from the central lighting station at Les Halles. The proprietors of this shop, being anxious to replace their gas by electricity, approached the town of Paris with a view of obtaining the necessary current from the municipal station. Our municipal authorities were so glad at the prospect of obtaining such a large order, that they immediately decided that this lighting should be undertaken for the sum of 80,000fr. per annum, which is the price now paid for gas. At first it was proposed to employ Ferranti machines for this purpose, which up to the present have not been brought into operation; but those responsible protested against the employment of 2,400-volt machines to carry out the lighting of an installation a few hundred metres distant. The installation at La Belle Jardinière will comprise 2,000 16 candle-power incandescent and 100 5-ampere arc lamps, representing a total of 145 kilo-watts. As each of the Ferranti machines has an output of 2,400 volts of 45 amperes, this installation alone would require one and a-half machines, leaving only about 80 kilo-watts available for all other customers, the third Ferranti machine being kept ready as a reserve. Moreover, as the shop in question closes at half-past eight, the average duration of the lighting would only be 2½ hours, so that lighting it by means of alternate currents would be a very wasteful proceeding. It is, therefore, now proposed to have recourse to a battery of accumulators to be charged during the day by the continuous-current machines, which are kept at work for the purpose of lighting the underground portion of the markets. The accumulators will always be in connection with the low-tension mains, and it is estimated that a battery of 100 accumulators weighing 200 kilogrammes each, together with the four Edison dyamos, would be sufficient to supply the 250 kilo-watts required for the 2½ hours' lighting at La Belle Jardinière.

La Compagnie des Forges de Creusot has purchased the Ganz patent rights for France; the Zipernowsky machines and transformers will, therefore, no longer be constructed by the Compagnie Continentale Edison.

CORRESPONDENCE.

ALTERNATING v. CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read with interest the Paper on "Alternating v. Continuous Currents in relation to the Human Body," by H. Newman Lawrence and Arthur Harries, M.D., in *The Electrician* of the 4th inst. I trust that a few remarks, if tardy, may not be out of place in connection with an important point raised therein.

While no one can dispute the well-known disparity between the resistance of a human body to continuous and rapidly alternating currents as measured by the Wheatstone bridge, it is unfair to attribute that disparity to any property peculiar to living organisms, unless, perhaps, in much lower degree; for the reason that the same or similar results are obtained if the measurements be made on bodies of animals lately killed, or on moist flesh preserved from the bodies of animals long deceased. The same phenomenon is noticed whenever a polarising electrolyte is measured such as an ordinary water voltameter, and is recognised to be the effect of the counter E.M.F. of polarisation upon the indications of the measuring instruments.

Several hundred observations of the resistance of persons have convinced me that such resistances are at any one time and under any given conditions fixed quantities independent of the strength, direction, or alternation of the measuring current when the effects of polarisation are eliminated. Of course the resistance will vary with the change of condition of the skin under immersion, &c.; but within the limits of observation, the resistance is not a function of the measuring current in strength or direction. In other words, the resistance with alternating currents will be that found in continuous currents.

To eliminate the effect of polarising E.M.F., which subsides with great rapidity on the cessation of the polarising current, it is necessary in using the Wheatstone bridge to balance to what may be called "instantaneous false zero," or such a position of the galvanometer needle as zero, that on releasing the battery key no further temporary throw of the needle in the direction calling for reduction of balancing resistance is discernible. The throw of the needle which generally takes place is evidently due to polarisation E.M.F.; and when this throw is just made to vanish by change of zero, the resistance (always much lower) unplugged for balance is correct. The method may be practised upon any ordinary polarising resistance, and it will be found that the resistance so obtained is independent of the battery power employed or the strength of current passing through the electrolyte. It is, of course, inaccurate when the resistance in any arm of the bridge contains sufficient electrostatic or electromagnetic capacity to produce a throw of the needle on its own account. I venture to believe that if the measurements of resistance offered by persons be made to instantaneous false zero, the

Digitized by Google

apparent disparity between the results with continuous or alternating currents will be found to disappear. If there be any due to a special property of living tissue, it will be of much lower order and lesser amount than that under present discussion. I have never been able to appreciate any difference with Wheatstone bridge ratio 1,000 : 1,000 between the limits of 2 and 8 volts of testing E.M.F.—Yours very truly,

Edison Laboratory, Orange, N.J., April 21, 1890. A. E. KENNELLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It seems that the language of my letter of the 8th inst. was somewhat too elliptical. May I therefore repeat more fully the two points which Mr. Lawrence takes up with an implication of careless reading and inaccurate quoting, which, I think, he can hardly sustain?

The measurements of resistance were made with "alternating currents from an induction coil." Unless this induction coil was really a transformer, *i.e.*, had an alternating current supplied to its primary (which is nowhere stated and is not usual), these currents differ widely from the alternating currents known to practical electrical engineers; and this difference is of such a kind and degree as to produce very different results in Wheatstone bridge measurements of such conductors as the human body, as Mr. Bláthy points out fully in your issue of April 24th. This difference is still more important as regards physiological effects; and it is this one fact which makes the title of the Paper misleading, and invalidates the conclusions as to the danger of commercial alternating currents sought to be drawn from the experiments therein recorded.

Secondly,—The tables. E. and F. appear to show that the average E.M.F. required to produce muscular fixation through dry-hand contacts of the ten persons experimented on was 6·36 volts effective. It is natural to inquire, what is the ratio between the muscular fixation E.M.F. and a fatal E.M.F.? I suggested ten times—under the same conditions, of course. I thought, and think, that this multiplier is large rather than small. Mr. Lawrence draws an analogy between E.M.F. and a dose of medicine. I know nothing of the latter subject, but I fancy that a doctor who had seen one grain of a drug produce temporary tetanus would not care to give a dose of ten grains to the same subject or to one in similar conditions.

To return; to say that 64 or even 100 volts of alternating E.M.F. can give a fatal or serious shock through dry-hand contacts is not borne out by experience; and I believe I am within the mark in saying that 400 to 500 volts is the lowest which has been proved to be fatal to human life. The lowest figure would give a ratio of about 63 times the muscular fixation E.M.F. deduced from the Paper under discussion, which seems extremely large. I take it that this question is one of serious importance, and worthy of accurate inquiry and unimpassioned discussion, which is my only excuse for occupying your space again.—Yours, &c., HENRY M. SAYERS.

Rua da Carvalhosa 79, Oporto, April 29, 1890.

THE DIATHERMANCY OF AIR IN RELATION TO THE EFFICIENCY OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to make a few remarks on Mr. Robertson's letter of last week. He has evidently misunderstood my Paper.

By omitting a part of a paragraph he makes it appear that I claim to have discovered something which has "been long known to lamp-makers and used as a rough test of the state of exhaustion."

I said, after the portion quoted, that not having seen any mention of the property in question, I did not know whether my results agreed with those obtained by others, meaning, of course, numerical results which would show the extent to which lamps were affected.

The variable properties of air in this respect were known before the invention of incandescent lamps, and are in some works stated wrongly.

The novelty in my method is that it affords a means of testing which can replace the "rough test" mentioned, and enable manufacturers to test the condition of lamps by an instrument much more sensitive than the bare hand.

Testing by means of sparks from an induction coil is a very imperfect and destructive method. A spark will only pass through a hole in ordinary glass, either one already existing, or one made, or enlarged by the spark itself, the effect being to cause steady deterioration of the vacuum in a lamp so treated.

My statement that lamps with a perfect vacuum attain and lose their incandescence slowly, while others with a less perfect vacuum behave differently, was based on my own observations; and if there are exceptions to this rule, then the property which air possesses of conducting heat more readily as its density increases must be in some cases suspended, as, for example, in the case of the carbon of high specific resistance mentioned in the concluding lines of Mr. Robertson's letter, which will increase in incandescence and as suddenly lose it in a medium in which another carbon performs both operations slowly.

The sudden loss can only be caused by the heat being more rapidly removed than from the other filament, and both being in the same medium makes this difference somewhat difficult to account for.

Mr. Robertson states that the differences in the state of exhaustion between two carefully made lamps are far within the $\frac{1}{10}$in. which I give. I purposely gave only the extremes of the scale; and as the difference between a highest possible and $\frac{1}{10}$in. vacuum is 215 divisions, it is evident the thermoscope would indicate the intermediate state with a little more accuracy than is possible in testing with the bare hand, and without waiting for the bulb to become heated by convection.—Yours, &c., F. HIGGINS.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Town Council of Godalming invite schemes and tenders for lighting that town by electricity. Particulars and estimates, endorsed "Tender for Lighting," should reach the Borough Surveyor by the 24th inst.

——— Tenders are required for the supply and erection of electric bells at the fire-engine station and in 11 firemen's dwellings adjoining, in Suffield-street, Middleton, and should be addressed to the Chairman of the Watch Committee, endorsed "Electric Bells," and delivered at the office of the Town Clerk, Middleton, by the 17th inst.

SALE BY AUCTION.—Tuesday, Wednesday, Thursday, Friday, and Saturday, the 13th, 14th, 15th, 16th, and 17th May, are the days fixed by Messrs. Wheatley Kirk, Price, and Goulty, for the sale of the valuable rolling mill, plant, machine, tools, engines and boilers, &c., &c., at the High and Low Mills Forge and Chain Works, Gateshead, at present in the occupation of Messrs. Hawks, Crawshay and Sons. The sale commences each day at 10 for 11 a.m. prompt. The catalogue of the sale, which is now ready, consists of 88 pages. Further particulars are given in our advertisement pages.

DISSOLUTION OF PARTNERSHIP.—The dissolution is announced of the partnership of Messrs. Stafford and Eaves, electrical engineers, of Coventry.

AMERICAN ELECTRICAL APPARATUS.—Messrs. Shippey Brothers, Limited, have been appointed sole European agents for the Viaduct Manufacturing Company, and inform us that they will, in future, hold stock in this country of the leading specialities manufactured by this firm. Show rooms have been opened for this department, and a number of new American electrical novelties are, we understand, on view.

ADMIRALTY CONTRACT.—Amongst the recent contracts given out by the Admiralty, one for the supply of a large number of projectors, search lamps, and switchboards, has been entrusted to Mr. Ronald A. Scott, of Acton-hill, W.

MAVOR AND COULSON.—This firm has just secured an important electric lighting contract in the city of Calcutta. The contract is for the lighting of the extensive suite of offices belonging to the British India Steam Navigation Company. It is probable that the installation will embrace about 300 incandescent lamps.

DORMAN AND SMITH.—This firm have recently received some large orders for abroad, one of which is for a consignment of electric light specialities, which includes 5,000 compound porcelain switches, and fuses of a total capacity of some 50,000 lights.

Digitized by Google

REMOVAL NOTICE.—The Ward Electric Car Company (Limited) have removed their offices to 38, Gracechurch-street, London, E.C., and have taken premises at Dacre-street, Westminster, S.W., where an experimental omnibus is on show.

PERSONAL.—Mr. J. D. F. Andrews has taken Mr. H. H. Gray, civil engineer, into partnership, and has removed his offices to 41 and 42, Parliament-street, Westminster, where the business of electric engineers will be continued, under the name of J. D. F. Andrews and Co. We understand Messrs. Andrews and Co. are now prepared to supply the trade with their various specialities.

MR. RICHARD CRITTALL.—Mr. Crittall has this week issued an illustrated catalogue of electric light fittings, containing a large number of ornamental designs in wrought iron, copper, brass, and copper and brass combined. The book is accompanied by a full list of prices, which seem very moderate.

THE ROYAL MILITARY EXHIBITION.—This Exhibition was opened on Wednesday last, in the large grounds of the Royal Hospital, Chelsea. The Exhibition will be lit by the electric light, the installation being in the hands of Messrs. Davey, Paxman, and Co.

STRODE AND CO.—We have received from Messrs. Strode and Company their catalogue, in which particulars are given of their dynamos, in Willan's patent combination frames, by which arrangement economy in space and fuel and silent running are obtained. The arrangement is specially adapted for ship lighting. The catalogue contains tables, tabulated price lists, &c., of electric light leads, cables, steam, gas, and petroleum engines, turbines, arc and incandescent lamps, projectors, and hand and automatic regulator lamps. A section of the catalogue is devoted to electric light fittings.

B. BACKHOUSE AND COMPANY (LATE MESSRS. P. F. BUCHNER AND CO.).—This firm, under date May 1st, announces that the reconstruction of the firm, which has been in progress since last autumn, is now complete, and that arrangements for the manufacture of artistic wrought-iron electric light fittings, &c., at their works at Munich are now perfected. These works, which have recently been considerably enlarged, are under the personal superintendence of Mr. Alfred Wahl.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The thirty-third ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Wednesday, under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. R. Collett) read the notice calling the meeting, and the minutes of the last meeting. The Report of the Directors was taken as read.

The CHAIRMAN: Gentlemen—I have nothing but congratulations to offer you on the state of your affairs which the Report and accounts disclose. During the half-year we have paid you a good dividend; we have largely increased your reserve fund, we have paid off a large portion of the first issue of debentures, and our income has been very satisfactory. I may state incidentally, what of course does not appear in the Report, that the income for the present year is in amount almost identically the same as for the same period of last year. Gentlemen, under these circumstances, I really have not much to say to you. One of my colleagues the other day said I always told you the same thing; but I do not think you will object to monotony when it is monotony of prosperity, and the figures are always on the right side. Our accounts show that there has been a slight increase of expenses this half-year, partly due to the necessity for making new buildings for the accommodation of our staff at some of our tropical stations, and partly to legal expenses incurred in London. The only other subject to which I wish to allude is the competition to which we may be exposed whenever our concession expires. Of course, we cannot prevent the Brazilian Government or any one else from starting a new line to compete with ours. All that we can do is to exercise the greatest supervision and care to see when the time arrives that you are in the best position to meet any competition that may arise. This constantly engages our attention, and I trust we shall be able to see you through the difficulty in a manner that will satisfy you With these observations I beg to move—

"That the Report of the Directors and the accounts to December 31, 1889, now submitted be approved and adopted."

Mr. F. YOULE seconded the motion.

Mr. GAMMON thought that a very large amount was being added to the reserve fund, which was all the larger remembering that the interest which it earned was added to that fund. More was being added to it than was being divided. He wished to ask whether they could give any idea as to the amount to which the reserve fund would be increased, and also whether any idea could be given to the shareholders when the £75,000 which they held in the African Direct Company was likely to yield them a profit.

The CHAIRMAN, in reply, stated that the dividend they had hitherto paid was not one that the shareholders could fairly complain of, and the Directors wished to retain in their own hands the right to increase the reserve to any point they conceived to be necessary. It was to be borne in mind that there was the chance of their having to renew either of the cables. The reserve, too, might become useful in equalising dividends, and in connection with competition a great advantage had been found in other companies to which he belonged from their having large reserves when competition had come upon them. The African Direct Company in the past half-year had brought them in traffic £7,318.

The Hon. ST. JOHN BRODRICK, M.P., added that the position of the African Direct Company, of which he was a Director, since the junction with the Cape had been very satisfactory. Without being able to make any actual promise, he thought they saw their way to paying a dividend on the shares. They had always paid the debenture interest.

Dr. TREWHELLA thought that the policy of the Company, which was a very good one for the most part, should not be altogether in reference to the future. He hoped that at their next meeting, which would be at the end of their financial year, a handsome bonus, more handsome than they had had hitherto, might be conceded to them. The reserve fund now amounted to £308,000, and he would like to know what rate of interest it yielded in the average.

Mr. GRIFFITHS: £3. 10s. 11d. per cent.

Dr. TREWHELLA said this reply corroborated his view that it would be an economy to pay off the Five per Cent. Debentures if they could do so, as in that way they would gain about 1½ per cent., representing the difference between what the investment of the reserve produced and the interest they paid on the debentures. He inquired when the concession would terminate.

Mr. W. S. CUFF said that they were all hoping to see a larger dividend, but at the same time he proposed that they should build up a reserve fund to very much more than it stood at now, even if they were not able to increase the dividend. He regarded the reserve fund as their backbone. The same idea had occurred to him which had been referred to by a previous speaker—whether they could not get rid of the debentures altogether.

The MANAGING DIRECTOR (Mr. Fuller) said that the monopoly which they had under the Brazilian concession would expire in August, 1892, but they had the power to lay cables as long as they liked. The Portuguese concessions would not expire till January, 1895.

The CHAIRMAN said he entirely agreed as to the advisability of diminishing the debenture debt, but it must be remembered that in this matter they were in the hands of the debenture-holders, who could not be compelled to sell their debentures or accept payment for them unless they were brought into the market. They would remember the suggestion which had been made as to the advisability of paying off debentures more rapidly, if they could possibly do so.

The CHAIRMAN put the resolution, and declared it carried unanimously.

Dr. TREWHELLA proposed, and Captain BLAKEY, R.N., seconded, a resolution passing a cordial vote of thanks to the Chairman and Directors for their efficient administration of the Company's affairs in the past.

The motion was carried, *nem. con.*; and the CHAIRMAN having briefly replied, the proceedings terminated.

The West India and Panama Telegraph Company (Limited).

The twenty-sixth ordinary general meeting of the members of this Company was held on Wednesday at Winchester House, Old Broad-street; Mr. C. W. Earle presiding.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting, and the minutes of the previous meeting, which were confirmed and signed as correctly entered.

The Report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—The Report is one which has caused me some disappointment. I do not allude to the falling off in the traffic, because in that respect we compare with a very large increased traffic in the corresponding period, which also showed a considerable increase upon the previous corresponding period. With regard to the increased expenditure for repairs, at this time last year I ventured to impress upon you all the more sanguine views I generally entertained as to our future expenses for the repair of cables. I was then under the impression that what we had done, and the large expenditure we had gone to, and the experience we had gained in the seas in which our cables lie, would have kept down the cost under this head. We find in this half-year that the expenditure has rather exceeded the recent average than been below it, a circumstance which has been somewhat disappointing. At our last two meetings it was urged upon us—and it was very natural that it should be so—to do away, if possible, with one of our two repairing ships. Well, during the year preceding this one we might, perhaps, have been able to get along with only one ship; but, as everybody knows who has anything to do with cables, the uncertainty as to their interruption from breaks or other accidents that may occur to them is very great, and it is impossible to tell what may happen. I will just now allude to the repair statement, and the secretary will show on the chart what cables were interrupted, with the view of your judging how far we could have done with only one ship, as was advocated at the last meeting. Up to the month of December we had only four interruptions to our twenty cables, and we thought we were going to have a good half-year; but on the second of that month the Jamaica Ponce cable was interrupted; this was followed by interruptions of the St. Thomas-San Juan and Jamaica-San Juan on the 6th, the St. Vincent-Grenada on the 13th, the Trinidad-Demerara on the 17th, and the Martinique-St. Lucia on the 18th. Now, with all these interruptions the only colonies that had been cut off from communication during the half-year were St. Lucia, St. Vincent, and St. Barbadoes for one day, and the colony of Demerara for 14 days. I think the rapidity with which these re-

Digitized by Google

pairs were made reflects great credit upon our captains and the officers under their command. But it is a very serious lesson that we learn from them, and shows how impossible it would have been to do with only one ship. The fact of these repairs having obliged us to put in no less than 77 miles of new cable, relieves us from the necessity of adding, as we should otherwise have done, to the reserve fund. The reserve fund is created for the purpose of renewing and keeping up the cables; and, of course, if you put in new cable to the extent of 77 miles, charging it to revenue, it comes to the same thing as if we put by sovereigns to meet the renewals. Our reserve fund now stands at the figure we calculated it would be in the present year, and therefore no addition has been made to it by the Directors this half-year. You will notice from the chart that the colonies of Barbadoes and Demerara, both of which are good customers, are only connected by single cables. These have been interrupted from time to time, causing much dissatisfaction, and stoppage of the subsidies, although we always put on sloops to carry the messages, and thereby, as far as possible, to keep up the communication. It has often been impressed upon us by these two colonies that we should extend to them the same advantages that the rest of our system enjoys; and with the view of consolidating our position in the West Indies we have decided to do so, provided that the Governments of these two colonies will assure us of their subsidies for a period of 10 years. Since the expiration of the original grants, they have only guaranteed a subsidy for one year, but we have told them that we could not think of putting down a second cable to connect their colonies upon such an insecure tenure as one year's subsidy, but that if we got it extended for ten years we should do so. Well, gentlemen, we hear that this proposal, after considerable negotiations, has been virtually accepted by these colonies, and we are now waiting the text of the Acts which they have passed in their Legislatures in order to proceed with the new work. I now come to what is, perhaps, the most interesting part of our Report—the reference that it makes to the new competitor that has stepped into our field of operations. Upon one occasion our Report, and I myself, from this chair, warned you that there was a danger looming before us by reason of the presence of French telegraphic interests in the West Indies. Some two years ago a French company laid down a cable to Venezuela. So long as it did not encroach upon our rights we were powerless. The next step taken by this French company was to lay a cable between Martinique and Guadeloupe. These are two of the colonies that hitherto gave us subsidies of £2,000 a year each. The subsidy of Guadeloupe has still several years to run; that of Martinique expired at the end of last year. At the beginning of the year the competing cable had not come into existence, and the colony of Martinique passed its subsidy to us for this year; but on this information reaching the ears of the French Colonial Minister, he sent out instructions ordering the Council at Martinique to re-assemble and reconsider its vote, as he had entered into a contract stipulating that the Martinique subsidy should go to the French enterprise from the beginning of the year; and that colony immediately revoked the grant of the subsidy which had previously been made to us. How far such an act is consonant with justice I will leave you to judge. We entered into a virtual contract for this year, and up to the present time have performed the duties of that contract; and yet, by a stroke of the pen they struck out the consideration upon the faith of which we rendered, and are rendering, services. The French are a very patriotic people, and they will do a great deal for their own country. Their Government assists them very substantially, as you will see by the action I have described, and which has been taken by the Colonial Minister in this matter. I wish that our Government and our Colonies would only show the same preference for English enterprise as the French show for theirs. You have probably noticed that there is shortly to be an International Telegraph Convention. These Conventions or Congresses assemble every five years in one of the capitals of Europe. They are called together by the telegraph departments of the different European Governments. The representatives of submarine telegraph companies are invited to attend these conferences without the right of any vote. I believe that the delegates of foreign Powers must listen to a certain extent to the views of those representing the telegraph cable interests, but they legislate according to their will. Hitherto we have not thought it necessary to incur the expense of sending any special representative from this Company, as some of the members of this Board, who are also Managing Directors of other Submarine Telegraph Companies, have hitherto been good enough to represent us at the same time that they were watching the interests of their own Companies. But on this occasion, what with the French complication and also the fact that the Spanish colonies have joined this international convention (and we are a great deal connected with the colonies of Spain, going as we do to Cuba and Porto Rico), it was thought advisable that I should attend the Conference this year. It was represented to us by the gentleman who is good enough to look after our interests in Paris, that on this occasion it would be important that the Chairman of the Company should proceed to Paris, an opinion endorsed by my colleagues on the Board. I may say that it was rather against the grain; but I have assented to do so, and I hope my attendance will have good results. A little earlier than this time last year I had to go to Madrid upon a question that arose there, and, through the valuable assistance of Sir Clare Ford, our Ambassador, I did something towards safeguarding the Company's interests. I now beg to move—

"*That the Directors' Report and accounts to December 31, 1889, submitted to this meeting be, and the same are hereby, received and adopted; and, as recommended, that a payment of a dividend of 6s. per share on the First Preference shares for the six months to December 31, 1889, and 27s. 6d. per share on account of arrears of dividend on the Second Preference shares, be, and the same is hereby, declared.*"

Mr. W. FORD seconded the motion.

A SHAREHOLDER asked what was the length of the Company's cables.

The CHAIRMAN replied that it was about 4,000 miles.

Mr. JAMESON asked whether the interest on the depreciation fund was added to that fund or included in the general revenue.

The CHAIRMAN: It is added to the depreciation fund.

A SHAREHOLDER asked to what extent the Company's traffic was affected by the French Company.

The CHAIRMAN said the line was only opened in February. It was only a local traffic, the whole of which came to only £400 a year, between the two islands, and the Company got part of it still. It was not a serious matter at present. It was the danger of extensions that the Company had to fear.

Mr. JAMESON: What is the length of the proposed new cables?

The CHAIRMAN: One is 100 miles, and the other 300 miles long.

Mr. ODELL asked what would be the probable cost of the new cables.

Mr. FORD said it would be very unwise to answer such a question.

The CHAIRMAN added that tenders for them would be invited in the usual way. They had got the money for them.

A SHAREHOLDER: The last repair was unexpected, was it not?

The CHAIRMAN: It was by me, because I said at the last two meetings that the cables had got into such a state that they would be less expensive to maintain. I was wrong, as you see, because we had these six breaks in one month.

Mr. FORD said it would be interesting to the shareholders to know that the expenditure on ships and cables during the last year had been very little in excess of the normal expenditure for the last 15 years. He had taken out the figures, and he found that the average amount paid under this head for that period had been £23,416, against £25,156 for the past 12 months. In some years the amount had been greatly in excess of that, showing how very much the repairs varied. For example, in 1882 he found they amounted to £35,600, in 1884 to £28,800, in 1886 to £28,000, and in 1887 they were £24,300, so that they were not this year greatly in excess of the average amount.

The resolution was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. H. WEAVER, Sir James Anderson was re-elected to his seat at the Board; as was also Mr. William Andrews, on the motion of the CHAIRMAN, seconded by Mr. H. HOLMES.

Mr. WHITE afterwards proposed, and Mr. CUFF seconded, the re-appointment of Mr. J. G. Griffiths as auditor of the Company.

On the motion of Mr. GOODSALL, seconded by Colonel MITCHELL, a vote of thanks to the Chairman and Directors was unanimously passed, and the proceedings terminated.

Submarine Cables Trust

The nineteenth ordinary general meeting of the certificate holders in this Trust was held at the offices, Winchester House, Old Broad-street, E.C., on Wednesday; Sir John Pender, K.C.M.G., presiding.

The SECRETARY (Mr. Lewis Wells) read the notice calling the meeting, and the minutes of the previous meeting, which were confirmed and signed as correctly entered.

The Report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, the accounts which we lay before you to-day compare very favourably with those which were submitted at our last meeting. The revenue has amounted to £23,094, against £19,118 in the previous year—an increase of £3,976. The expenses have been £1,274, as against £1,383, a diminution of £109. We are, therefore, some £4,000 better off than we were this time last year. As stated in the Report, the certificate holders have received interest at the rate of 6⅜ per cent. this year, compared with 5⅝ per cent. last year. We hope to continue to pay at the same, or at a higher rate, until we have liquidated the coupon which is now in arrear. We shall then revert to the regular interest of 6 per cent. which, under our trust deed, is cumulative. As you know, gentlemen, the revenue of this Company depends entirely upon the prosperity of the other submarine companies in which our capital is invested. We are all, I may say, at the present time working in harmony. There is no active competition, and consequently there is no cutting of rates; as long as we work in what I may call this satisfactory business style the chances are that the shareholders will be largely benefited. I have often said, and I repeat it here, that submarine telegraphy is becoming a necessity to the nations of the world. People that use it cannot give it up; and there is always a new *clientèle* cropping up which finds that to live in business the telegraph must be used. Therefore, believing in the progress of trade throughout the world, and seeing that our submarine system touches every civilised part of the world, I think that the Trust is in a very sound position. With these remarks I beg to move—

"*That the Report and accounts of the trustees now submitted to the meeting be approved and adopted.*"

The Most Hon. the MARQUIS OF TWEEDDALE seconded the resolution, which was carried unanimously.

Mr. JEFFERSON proposed, and Mr. CASHMAN seconded the following resolution:—

"*That Mr. John G. Griffiths, F.C.A., and Mr. John Gane, F.C.A., be re-elected auditors to the Trust for the current year, and that their remuneration be the sum of £25 each.*"

On the motion of Mr. JEFFERSON, seconded by Mr. CASHMAN, a vote of thanks was unanimously accorded to the Chairman and Trustees for their conduct of the business of the Trust during the past twelve months

Digitized by Google

The CHAIRMAN: On the part of my colleagues and myself, I can truly say that there is no greater compliment that you could pay us than to accept our Report with the few remarks I have made to you as being satisfactory. It shows that you are satisfied, and that you believe that we are doing the best we can for the interests of the Trust. That is very gratifying to us, and we shall continue to act in the same way to command the support and confidence of our shareholders on occasions like this.

The proceedings then terminated.

The House-to-House Electric Light Supply Company (Limited).

The second ordinary general meeting of the proprietors was held at the Central Electric Lighting Station (Kensington), Richmond-road, S.W., on Monday last; Mr. Henry Ramié Beeton presiding.

The SECRETARY (Mr. H. St. John Winkworth) read the notice convening the meeting, and the Report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—In accordance with the Articles of Association the Report and accounts have been issued to every shareholder, so that I shall probably be consulting the convenience of the meeting if I take them as read, and proceed at once to recommend them to your adoption. The first observation I have to make in regard to the accounts is that in the early stages of our business the capital expenditure is necessarily out of proportion to the earning capacity, for the reason that we are called upon to meet, in the nature of the case, a progressive demand, and the form of supply which is most economical in the case of a large demand is different from that in the case of a small one, so that we are practically obliged in the first instance to adopt a capital basis, which is adapted to an ulterior, rather than to an immediate, revenue. This being so, the justification of our accounts is to be sought at a point which is more or less removed; and we must be content to-day, if we are in a position to predicate with certainty that our profits will be such as to permit of a reasonable dividend in the near future, with the assurance of an improvement later on. Now, our present plant is equal to the supply of twice, and our capital capacity is equal to the supply of three times, as many lights as we have on our existing circuit, and this, notwithstanding the fact that we have connected on an average about 1,000 lights per month. I think that these figures are evidence that our progress up to the present has been satisfactory, and I think also that we may look forward to a steady progress in the future. It is always dangerous to prophesy, and never more so than in the case of a new industry in which the conditions are without precedent, and in which, of course, very limited experience is available to guide us; but I can say, with some degree of confidence, that if the rate of progress which has prevailed in the past is maintained in the future, in twelve months from to-day we shall be in the enjoyment of a demand which will ensure us a fair dividend on our capital, and in two years from the present time our profits will be as much as it would ever be prudent to distribute (applause). Of course, we naturally wish that our progress had been greater than it has been; but even in a rich residential district like ours we find that there are many causes which operate to deter custom. In the first place it is our peculiar misfortune that we have to suffer instead of benefiting by the faults of those who are engaged in the same line of business. It is unfortunately true that whereas we have never had a failure of the light, yet the fact that some of the more prominent supply companies have notoriously blundered has deterred many people even in our district from becoming customers. They naturally hold off until they can feel more assurance of continuous and reliable lighting. Then, again, we have to contend with the expense of installing the light, which, of course, operates with added force during the lifetime of existing gas fittings, and during the unexpired portion of short leases; and lastly, we have been prejudiced by an unfounded scare, which has been fostered by interested and unscrupulous persons, of the danger of the current. But, notwithstanding these obstacles, we have confidence in the future of electric lighting. The electric light is healthy and it is clean, and these are advantages which many can afford to pay for, and which when an increased demand enables us to reduce the cost of production, we hope to bring within the reach of a greater number. As an indication of the confidence which is felt by our neighbours in our future, I may mention that, so far as we are aware, every new building in the district is being wired for the electric light, and no gas pipes are being admitted at all. Moreover, we are in a position not only to supply both arc and incandescent lighting, but also motive power, and already among the business premises which we serve we have been asked to provide for this class of custom. I am afraid that some of the shareholders have felt that their attendance here to-day has been somewhat of an inconvenience to them, but the Directors felt that it would be an advantage that they should be able to visit the district and inspect the station. Whatever anybody else may say about us, I think everyone will recognise the excellence of our station; and, after all, mechanical efficiency is at the foundation of prosperity in this business. Our dynamos, which I hope you will see soon, are working now, as they have always done—noiselessly, and with the minimum of supervision—and they have never had any repairs, and, indeed, no work whatever has been spent on them since they started. The excellence of our work, and the unrivalled experience of our engineers, have induced us not only to anticipate success in the field of supply, but also to look forward to building for others similar stations to that which we have built for ourselves. We believe that those who are engaged in overcoming the daily difficulties of supply, and who are called upon to meet the constantly varying conditions of the industry, are best qualified to undertake the work of construction—that no engineer, whatever his theoretical attainments, and that no Construction Company, however extensive its works and resources, can compete in the knowledge which is necessary to the successful establishment of a central station with those who, like the engineers of the House-to-House Electric Supply Company, have been engaged in planning and constructing the earliest and most successful stations, and in conducting their operations ever since. Possessed of these qualifications and encouraged by the action of the Board of Trade in allotting the metropolitan area, we have been forming provincial companies with a view to developing electric lighting generally, and promoting the system and interests of the House-to-House Company in particular in other cities and towns of the United Kingdom. To this end we have appointed qualified agents, who have visited our stations, who have acquired a knowledge of the industry, and who have formed confidence in us. These agents, acting on behalf of such companies, have sought the permission of the local authorities in all the principal centres to apply for statutory powers, and in so doing they have neglected no opportunity of bringing the merits of our station under the notice of deputations from the local authorities. We hope and believe that the expenditure which we have incurred in this direction will bear good fruit; and in support of this expectation, I may mention that we have already obtained the requisite sanction of many local authorities, and in other cases where such sanction has been withheld, we believe that, if the authorities undertake the lighting themselves, we shall get the erection of their station; and if they neglect to apply for statutory privileges, we have the assurance of the Board of Trade that in any application for a Provisional Order which we ourselves may make, due regard will be had to the fact that we have been at considerable expense, and that we have complied with the rules of the department. With the growth of this branch of our business the Directors are of opinion that it will be desirable to separate the supply on the one hand from the engineering or construction on the other; and they have had several plans under consideration to this end, which when the time comes they will submit to the shareholders. With these few observations I beg to move—

"*That the report and accounts be received and adopted*" (applause).

Mr. ROBERT HAMMOND (Managing Director) said he had very great pleasure in seconding the resolution. He felt after the exhaustive speech which the Chairman had made, there was very little else to be said; but he would like to draw the attention of the shareholders to one or two points in the report, and to emphasise them. The first was that they had only for a very short time been in possession of Parliamentary powers. It was true that the Company was formed two years ago, but it soon became apparent, with the very stringent rule which the Board of Trade put forth in reference to overhead wires, that the Company's system of supply must be by means of underground mains; and though they had made application to the vestry in June, 1888, various forms had to be gone through before they could finally get what they had, at the present time—an Act of Parliament, and practically they did not start their station till November last. Under these circumstances, he must say he was inclined to take a very much more sanguine view of their recent progress than the Chairman had ventured to do. In the first place, however, he fully agreed with what Mr. Beeton said that it would be absurd at the beginning of a 42 years' tenure under an Act of Parliament to judge of their future business by the start of only a few months. Having pointed out by means of a chart the growth of the number of the Company's installations from November to the end of April last, he proceeded to say that it would be fair to postulate that what had occurred in that period would happen again, and much more rapidly as the months passed by; and they might fairly say, that, having arrived at a state of things when they could claim that they had now got a revenue which covered all their working expenses and their establishment charges, they had done extremely well after practically six months' working, and at the outset of a career that would run for 42 years (applause). He felt that at the end of another year they would find that their present works would not be sufficient to cope with the demands made upon them; and, as foreshadowed in the report, they would have gradually, as the business developed, to increase their machinery. Going back to the formation of the Company he would point out to the shareholders that the Directors had absolutely carried out the programme which had been laid down. That programme was that the Company was established for the purpose of founding supply stations. It was not established, as most electric light companies were, for the purchase of patents. That was carefully avoided. They found themselves bound to no system at all, and the money which they asked for, and which had been subscribed, had been used for the purpose of founding electric lighting stations. They first founded the station where they now were as a sample of the work they were able to do, and then they prepared the ground for a number of sub-companies, which it was to be hoped would bring them an amount of business; so that on all hands they had carried out the proposals with which they started. Another matter which had not been alluded to by the Chairman, and which did not find a place in the Report, was the fact that not a single Director had received any fees since the establishment of the Company (applause). It was not often that a report came before shareholders in which no Directors' fees appeared; but it was felt by the Board that until the business was thoroughly established they would not call upon the Company to pay the fees which under the Articles of Association were due to them. This circumstance seemed to him to show that the Directors had the very best interests of the Company at heart; and speaking as one who had been enthusiastic in the direction of the electric light supply from the beginning, and who had been connected with the early lighting stations, such as those at Eastbourne and Brighton, he looked forward with a great deal of confidence to the future of the Company (applause).

The resolution was carried unanimously.

On the motion of Mr. JAMES WHITEHEAD, seconded by Mr. W. PAGE, the retiring Directors, Mr. Beeton and Mr. Hammond, were unanimously

Digitized by Google

re-elected ; as were also the auditors, Messrs. Theobald Bros. and Miall, on the motion of Mr. PAGE, seconded by Mr. WHITEHEAD.

The company afterwards visited the station, all the details of which were carefully explained by Mr. Hammond and Mr. Hall.

The West Coast of America Telegraph Company (Limited).

The following is the Report of the Directors of this Company for the year 1889, to be presented to the shareholders at the thirteenth ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 14th inst., at 1 o'clock :—

The gross income of the Company for the year ending 31st December, 1889, was £84,457. 13s. 1d., against £65,714. 15s. 4d. for the year ending 31st December, 1888. Adding £480. 3s. 9d. brought forward from previous year, makes £84,937. 16s. 10d., and after deducting from this the Debenture interest and all other charges, and the two dividends of 5s. each, paid in July, 1889, and January, 1890, respectively, there remains the sum of £30,517. 10s. 3d. Out of this amount, the Directors have transferred £25,000 to the reserve fund, bringing it up to £64,000 ; and recommend the distribution to the shareholders of 2s. per share as bonus, payable on May 21st, to write off £2,000 from the value of the repairing steamer Retriever, thereby reducing her valuation in the books of the Company to £15,000, and leave £517. 10s. 3d. to be carried forward.

The Directors considered it prudent to add the above large sum to reserve owing to renewed threats of competition, which, if carried out, would considerably diminish the revenue of the Company. The land line to Santiago, mentioned in last year's Report, has proved a satisfactory investment. The cables and repairing steamer are kept in perfect working order.

Mr. Henry Roberts and Mr. Frederick Walters are the Directors retiring in rotation ; both are eligible, and offer themselves for re-election. The auditor, Mr. J. Weise, of Messrs. Turquand, Youngs and Co., retires, and is eligible for re-election.

Maxim-Weston Electric Company (Limited)

The following is the Report of the Directors to be presented at the ordinary general meeting of the Company, to be held this day (Friday) at the Cannon-street Hotel, London, E.C., at 12 o'clock.

The Directors have delayed calling the shareholders together in anticipation of being able to report the result of the action against the Managing Director of the late Company. That action is, however, still pending. The Directors, in consequence, are unable to comment upon matters which are still the subject of litigation, and refrain from now giving to the shareholders so full an explanation of the position of the Company as they would wish. The Directors share in the regret which must be felt by every member of the Company, at the result of the Company's operations. The two Directors retiring under the Articles of Association are Messrs. John Marks and James G. Couchman. The auditors, Messrs. Boyce and Ramsay, retire in accordance with the Articles of Association, and offer themselves for re-election.

We give below the extraordinary balance-sheet accompanying the Report, which, as an historical document, is well worthy placing on record in our columns. The footnotes appended by the Auditors are specially worthy of notice. The balance-sheet is dated April 28, 1890, and, as will be seen, is a statement for the period from January 17th to December 31st, 1889 :—

AUDITORS' REPORT.

We have examined the accounts of the Company for the period from the 17th January, 1889, to 31st December, 1889, and compared the accompanying balance-sheet with the books, and beg to report as follows:

The plant, machinery and stock have been valued at the same prices at which they were taken over from the previous company. Nothing has been allowed for depreciation.

The patents are put down at £26,500. This is the nominal amount which they cost the Company, such amount representing the difference between the estimated value of the assets and liabilities of the previous company at the date of the transfer.

We are informed that many of the patents had been allowed to lapse prior to the formation of the present Company, and that a lawsuit is pending with regard thereto.

The book debts of the previous company unrealised, amounting to £4,940 13s. 6d., include goods in the hands of Agents abroad, and cash deposited in the bank and in Court pending the result of the Watt actions. Of this amount only a small proportion can be considered good.

A reserve fund was created at the date of the transfer to the present Company, to cover any deficiency that might arise on the realisation of the previous Company's assets and the costs of re-construction. To this account have been charged all losses upon the realisation of such of the book debts as had been settled up to 31st December, 1889, the costs of re-construction, claims upon the previous company paid, and £157 10s. voted by the shareholders as the remuneration of the Liquidators. The balance of £1,939 9s. 3d. remaining to the credit of the reserve fund is not sufficient to meet the deficiency upon the remaining book debts of the previous company, and the cost of pending lawsuits.

Subject to the above observations, the balance-sheet sets forth the position of the Company's affairs as shown by the books on the 31st December, 1889.

(Signed) BOYCE AND RAMSAY,
Chartered Accountants,
(Auditors to the Company).

NEW COMPANIES REGISTERED.

ST. ASAPH IRON, LEAD AND BARYTA COMPANY (LIMITED).—Registered by Richard Chandler, 66, Bishopsgate-street, E.C., with a capital of £30,000, in £1 shares. Object: To purchase, lease, or otherwise acquire land, whether or not for mining purposes, mines, mining rights, water rights, electric power rights in Great Britain or elsewhere.

THE ELECTRIC WELDING COMPANY (LIMITED).—Objects: To acquire inventions, patents, rights, and concessions, for, or in relation to, the utilisation and employment of electricity and any other power for the production and distribution of electric currents, adopting, therefor, an agreement to be made with Edmund Fitzmaurice Lenon, the particulars whereof are not specified in the Articles of Association. Capital £460,000, in £10 shares, of which the first 1,000 are founders' shares. Borrowing limit, one half subscribed capital. Registered, May 1st, by Ashurst, Morris, Crisp, and Co., solicitors, 6, Old Jewry, London.

CITY NOTES, &c.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of April were £3,600, as compared with £4,060 in the corresponding month of last year. The receipts for the month of January, estimated at £3,150, realised £3,176.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of April amounted to £2,089, against £1,867 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of April were £40,696, as against £42,709 in the corresponding period, showing a decrease of £2,013.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of April, 1890, amounted to £55,042, as against £51,452 in the corresponding period of 1889, or an increase of £3,590.

EXETER ELECTRIC LIGHT COMPANY.—We have received this week a prospectus of a further issue of 500 shares of £10 each in this Company. The prospectus sets out that the new issue is intended to provide capital for a considerable extension of the Company's plant and operations. The Directors state that they have large orders on hand for the supply of electricity. The installations erected by the Company have given general satisfaction. £2 is payable on application, £2 on allotment, and the balance of the £10 on the 31st July next. The prospectus does not indicate when applications will close.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of April amounted to £21,600. From the 1st January to 30th April these receipts amounted to £81,800, against, in the corresponding months of 1888 and 1889, £85,200 and £84,000 respectively.

THE MUTUAL TELEPHONE COMPANY (LIMITED).—This Company has been formed with a capital of £100,000, in 10,000 shares of £10 each. The present issue is 4,500 shares of £10 each, payable £1 on application, £1 on allotment, and the balance in sums not to exceed £2, at intervals of not less than two months. Shares are to be allotted in preference to those undertaking to rent this Company's telephones. The Directors are A. D. Provand, Esq., M.P.; H. T. Gaddum, Esq., J.P.; W. M. Mollison, Esq.; J. R. Paton, Esq.; Councillor James W. Southern. The Company holds a licence from the Postmaster-General, and negotiations are in progress for the opening of exchanges in Yorkshire, Liverpool, London, and the Midlands. The Secretary (pro. tem.) is Mr. J. Vincent Swindells, with offices at 71, King-street, Manchester. The prospectus states that the object of the Company is to provide first-class telephone service, both public and private, and for these purposes the Company intend to undertake the following different kinds of telephonic services:—1. Exchange wires (not exceeding one mile from Central Exchange, Manchester) at £5 per annum to holders of two or more shares and £6 per annum to other renters. (For distances beyond one mile an extra charge will be made.) 2. Extra instruments in other rooms of the renter's office or warehouse for attaching to the Exchange wires at £1 each per annum. 3. Telephones from one part to another of the same building, requiring two instruments, at about £2 per annum. 4. Telephones communicating from one building to another, or between warehouses and works at a distance. These would require two instruments and the communicating wires, and would be charged according to distance. The Directors further announce that they intend at the earliest possible date to establish a complete system of inter-town communication.

STOCK EXCHANGE.—Application has been made to the Committee to appoint a special settling day in the:—Ordinary shares, Nos. 1 to 31,436, and Preference shares, Nos. 40,001 to 54,285, of Woodhouse and Rawson United (Limited); and to allow the following securities to be quoted in the Official List:—Western and Brazilian Telegraph Company (Limited)—further issue of 489 shares, Nos. 91,559 to 92,047.

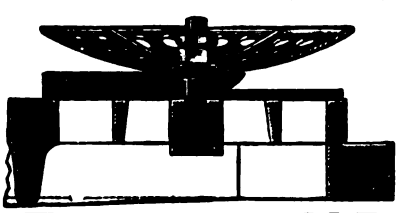
VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—The prospectus of this venture has been issued this week. The present issue is of £70,000 Five per Cent. First Mortgage Debentures of £100 each (at 85 per cent.) and for 70,000 £1 shares. The Directors are Sir Douglas Fox, Francis Bennoch, Esq., J. W. Philipps, Esq., M.P., and W. P. van Laar, Esq.; the Manager in Venezuela is James A. Derrom, Esq. (formerly manager of the Inter-Continental Telephone Company); the consulting engineer is Dr. John Hopkinson, F.R.S.; the secretary is John Simpson, Esq.; and the offices are at Winchester House, Old Broad-street, London, E.C. The Company takes over the business, which is in full working order, of the Inter-Continental Telephone Company of New Jersey, U.S.A., and a Venezuelan Government Concession. The Company's system aggregates in length about 1,200 miles, and covers the larger part of the Venezuelan Republic. The number of subscribers on February 28th last was 1,511, and the net revenue for 1890 is estimated to produce about £8,200, leaving a surplus available for dividend of £4,700.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month ended April 30th were £5,275.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended April 30th show an increase of £197 as compared with the corresponding period of last year.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 626.—Vol. XXV. FRIDAY, MAY 16, 1890. Price Fourpence.

NOTES.

The discussion which arose on Dr. Lodge's Paper at the Institution on Thursday last was noteworthy, not only in consequence of the value of the results of experience brought forward, and for the suggestiveness of many of the speeches, but even more so for the conciseness of the remarks themselves. It was, indeed, rather a pity that a discussion of so high a character should have been brought to a close before showing any signs of flagging, although, no doubt, the desire of the President to end the proceedings at a reasonable hour did much to contribute to the brevity and pointedness of the remarks. If the same results could be always thus brought about, the shortening of the discussion would be attended with two advantages: it would not only raise the standard of the remarks; but, what is more important still, it would render it possible for more Papers to be read in the course of the Session. The number of Papers read during the year at the Institution of Electrical Engineers is still remarkably few, although greater than used to be the case.

The remarks which were made did not refer so much to Dr. Lodge's protector as to those the capabilities of which have already been tested by long use. Even Sir William Thomson was no exception; for, although fully recognising the theoretical merits of the new lightning guard, he preferred to speak about the existing methods of protection, and expressed the opinion that the most reliable way of safeguarding a cable from the effects of lightning was by means of a fine wire such as is used in the Saunders protector. The suggestion of Sir William Thomson that a condenser could be used in series with the fine wire, when considered in connection with Mr. Saunders' statement that in the whole of his unique experience he had known no case of injury caused by lightning to condensers connected with cables, naturally leads us to inquire to what extent condensers can be subjected to alternating potentials without injury. The subject is one about which very little is known, and which will become of increasing importance as alternating-current devices depending on the use of condensers are more and more developed. The frequency of the alternations caused by a lightning discharge is so enormous that the potential absorbed by the condenser in developing a moderate current need be very little, and the risk of a breakdown is consequently but small. It would be far otherwise if the oscillations were slow, for the condenser might then absorb all the potential of the flash. Thus a microfarad condenser will only need one volt at its terminals to pass a current of 600 amperes if the alternations are as frequent as 100 million a second, but if the frequency is only 100 a second it will require a million volts to produce that current

Dr. Lodge's protector seems no exception to the rule that there is nothing new under the sun. Prof. Hughes, in the course of his interesting remarks, succeeded in showing that several existing forms of lightning-guards were essentially the same in principle as that of Dr. Lodge, although the principle on which they are based has not till now been recognised.

General Webber justly complimented Dr. Lodge on the suggestive nature of his Paper, and the various speakers bore practical witness to the truth of the remark by directing the discussion to an important matter, alluded to by the author, and on which we commented last week, viz., the protection of electric lighting circuits from the effects of lightning. Prof. Ayrton pointed out the unsuitability of fine wire protectors for such purposes; and Mr. Mordey remarked that the chief danger was of an indirect nature, and arose from the dynamo current following the arc started by the flash.

Although the exhibits at the Royal Society's *soirée* yesterday evening comprised little that was absolutely novel, they were of considerable interest, and a very large proportion of them were of an electrical character. Several of the exhibits have recently been brought before the Physical Society, notably the magnetic survey maps of Profs. Thorpe and Rücker, Prof. Silvanus Thompson's new optical rotator, and Mr. Gregory's electric radiation meter. Mr. Shelford Bidwell showed his experiments on the electrification of a steam jet, and Mr. Vernon Boys' series of photographs taken by electric sparks attracted much attention.

Among the exhibits of a more practical nature were various forms of Dr. Lodge's new lightning protector, and a new material for bushing shafts shown by Mr. Killingworth Hedges. This consists of a mixture of steatite and carbon, and the bushings can be put in just as cast, giving no further trouble for lubrication. They were shown fitted to very fast running shafts. They require renewing after a time, but meanwhile the expense and trouble of lubrication are avoided. Mr.

Digitized by Google

SYMONS also exhibited a very elaborate apparatus for recording the various disturbances during a thunderstorm.

PROF. ROBERTS-AUSTEN experimentally showed the recalescence phenomena occurring during the cooling of iron and steel, by the aid of a thermo-electric joint of very simple construction, which seems admirably suited for the measurement of high temperatures, since it is very sensitive to rapid changes of temperature, and may be calibrated by the air-thermometer to any desired degree of accuracy. A very complete exhibit of apparatus was also shown by Mr. G. BURCH, illustrating the use of the capillary electrometer for investigating rapid changes of potential.

THE obscurity which surrounds many phenomena connected with alternating currents will be in some measure cleared up by an attentive study of Dr. FLEMING'S Paper "On Prof. ELIHU THOMSON'S Electro-Magnetic Induction Experiments," which we reproduce in this issue. The effect of self-induction in retarding the phase of Foucault currents, and consequently causing magnetic repulsion between the inducing and induced currents, was first called attention to by Dr. FLEMING in connection with his galvanometer for alternate currents; but it is to the interesting experiments of Prof. THOMSON that we mainly owe our present knowledge of these intricate phenomena. The very striking nature of the results obtained is in itself sufficient to draw close attention to the experiments, irrespective of the many important applications to practice which may result from them, one of which, the WRIGHT-FERRANTI meter, we describe in another column.

IT is worth while, in connection with this subject, to recall the mechanical interpretation of electro-magnetic repulsion according to the radiation theory of electricity. It was a prediction of MAXWELL that any electro-magnetic radiation, such as a beam of sunlight, would repel any body on which it fell, and at the surface of which it was reflected or absorbed. In Prof. THOMSON'S experiments the radiation proceeds from the primary to the secondary circuits, and the repulsion between them arises from the mechanical reactions due to reflection at the surface of the secondary coil.

THE important task of verifying some of Prof. THOMSON'S results by careful measurement has been undertaken by M. BORGMANN, who, in a number of the *Comptes Rendus*, describes several quantitative results he had obtained. The primary magnetising current was measured by a SIEMENS dynamometer, and the repulsive forces exerted on a disc were weighed by means of a delicate balance. The repulsive force was found proportional to the mean square of the primary current; it diminished as the distance between the disc and magnetising solenoid increased; it diminished with the diameter, and increased with the thickness of the disc. For discs of the same dimensions, but of different metals, the repulsion diminished with the specific resistance, although in a less proportion, owing to self-induction; and, as the frequency of the current was increased, the forces were found to diminish, the product being about constant. Although several of these results are only what theory would have predicted, it is the first time they have been experimentally shown.

IN another column will be found an interesting paper by M. SPECNEW upon the influence of electricity on vegetable growth. The scale on which M. SPECNEW'S researches were carried out and the period over which they extended impart more than a purely scientific interest to the striking results obtained by him, though the day when the British farmer will increase the productiveness of his land by placing it within an electrified wire cage is perhaps somewhat distant.

WE have received from the LANE-FOX Electrical Company a pamphlet containing reports from several eminent authorities upon the LANE-FOX patent, No. 3,988, of 1878. In its final form this patent merely claims the employment of secondary batteries as "reservoirs of electricity," in conjunction with lamps run in parallel across constant potential mains. The reports in question, which are dated 1886, all agree as to the originality and utility of the system of distribution which was proposed in 1878 by Mr. LANE-FOX; and on this point indeed there is probably general agreement. We understand, however, that the LANE-FOX Electrical Company has been formed, amongst other things, for the purpose of exacting royalties from those whom they consider to come within the scope of this patent Whatever the reasons may have been, the fact remains that this LANE-FOX patent has for twelve years been kept in comparative obscurity, and is now flourished in the faces of those who have laboriously worked out the essential details of a system of which the bare outlines only were shadowed forth by Mr. LANE-FOX. Under these circumstances, therefore, it is perhaps satisfactory that the patent will expire within the next two years.

IN his interesting Paper on "The Aim and Scope of Higher Technical Education," read before the Society of Arts last week, Prof. PERCY F. FRANKLAND urged our old universities, with their immense *prestige*, to adapt themselves to the needs of the present industrial era by developing their teaching in the direction of higher technical education. As Prof. FRANKLAND remarked, the training at present in vogue at Oxford and Cambridge tends to engender a distaste for the practical; yet a large proportion of those who are trained in this manner have ultimately to take to some practical career. In its laudation of German methods and organisation, Prof. FRANKLAND'S Paper resembled many others on the same subject. If ever technical education comes to be recognised in this country in a manner satisfactory to its advocates, it is to be hoped that this admiration for what is German will not result in mere imitation, and to the sacrifice of freedom and originality for the sake of a rigid uniformity of instruction.

THE "startling conception of the human race united in bonds of instantaneous intercourse" is due, we need hardly say, to the brain of Mr. HENNIKER HEATON, who, in *The Times* of Saturday last, *apropos* of the Paris Telegraphic Convention,

Digitized by Google

explains to the British public how easy it would be to reduce international telegraphy to a penny per word. Between Great Britain and France, Holland, Belgium, and Germany, he is sure it could be done at a profit; and he arrives at this gratifying result by adding the respective local charges together and ignoring the cables. A similar process of reasoning, with a dash of personal bias against the proprietors, would reduce the cable charges to British India and the Colonies correspondingly. There may be something to be said for cheapening international telegraphy, just as something may be said for reducing international Customs. Mr. HENNIKER HEATON might address himself to the latter question with advantage to his object; for at present every Government is in the habit of taxing foreign telegrams much as it does foreign products and manufactures, and probably for the same reasons. Mr. HEATON thinks that the Government telegraphs should not be worked for profit. Possibly the Governments might agree with him; but what they would say is, that telegraph business conducted as a means of raising revenue is a very inoffensive form of indirect taxation, and that if this were abandoned something else would have to take its place.

THE validity of contracts made by telephone has recently been called in question before the United States Courts. In an action brought by the Paddock-Hawley Iron Company against Messrs. PULLIS BROTHERS, it appeared that some iron was ordered by telephone, but that when the bill was sent in Messrs. PULLIS BROTHERS demanded a reduction of some 10 per cent., in virtue of an agreement to that effect which they said had been made by telephone. In reply to this the plaintiffs asserted that there were only two members of their firm empowered to make such contracts, and that neither of them ever heard of this telephonic communication until after the controversy arose. The Court held that while a teleponhic contract was as binding as any other, the same rules of evidence applied; and as there was not sufficient evidence to disprove the assertion of the plaintiffs, it was decided that the bill must be paid in full. The moral obviously is, avoid making contracts through the telephone alone.

Folkestone.—The Corporation has granted Messrs. Crompton and Co. an extension of time for completing the electric light until December 31st.

The Lighting of the City.—The House-to-House Company have given notice of their intention not to proceed any further this Session with the Bill deposited by them for power to supply electricity within the City.

Dublin.—At the last meeting of the Corporation the report of the Electric Lighting Committee recommending the utilisation of some Corporation land in Fleet-street as a site for a central station, was adopted.

Bolton. — The Town Council were on Tuesday informed by the Board of Trade that the application of the Lancashire and Cheshire House-to-House Electricity Company for the Provisional Order had been refused.

Dewsbury.—At the last meeting of the Town Council it was decided, on the recommendation of the Gas and Water Committee, to apply for a Provisional Order to enable the Council to supply electricity within the borough.

Electric Signals for Mines.—A special monthly meeting of the National Association of Colliery Managers was held on May 3rd, at Messrs. John Davis and Sons', All Saints' Works, Derby. The hall was arranged with specimens of Messrs. Davis's apparatus for electric signalling in collieries.

Conference of Australian Postmasters-General. — A conference of the Postmasters-General of all the Australasian Colonies, with the exception of New Zealand, will, says a Reuter's telegram, meet at Adelaide on the 20th inst., to consider, amongst other things, the question of cable rates.

National Telephone Electrical Society.—On the 2nd inst., the members of this Society held their first annual *conversazione* at the Colonnade Hotel, New-street, Birmingham. In the course of the evening Prof. J. H. Poynting (one of the local directors of the National Telephone Co.) showed some very interesting and novel experiments.

London Chamber of Commerce.—Amongst those elected members of the London Chamber of Commerce at the last Council meeting were C. A. Parsons and Co., electrical engineers; Shaw and Connolly, electrical engineers and cable manufacturers; and Montagu J. Scott (Montagu J. Scott and Co.), electrical engineer and contractor.

The French Telephones.—The committee nominated by the French postal telegraph department to study the question of improving the telephone service have tested 20 different transmitters on the Paris-Brussels trunk wire (424 miles). One instrument proved itself decidedly the superior, and 50 of this type will now be used experimentally at Paris, Marseilles, and Lille.

Vacant Appointment.—The Committee of Management of University College, Nottingham, require the services of a properly qualified Professor of Engineering, who will have charge of the new technical schools and engineering laboratories. The salary is £300 a year, with a share of the fees, guaranteed at £100 for the first year. All further particulars may be obtained of the Town Clerk, Guildhall, Nottingham.

The Railway Rates Inquiry.—A Correction.—In the report in our last issue of the proceedings before the Board of Trade Inquiry into the question of Railway Rates, Mr. A. P. Trotter is represented as saying that the value of cotton-covered wire was about £72 per ton at the present moment. The sentence, on p. 15, should read: "Cotton-covered wire is worth about £90 per ton; the price of the bare copper wire being about £72."

The West of England Telephone Company.—Arrangements have been made by this Company by which all the principal Government offices at Devonport are placed in communication with the Telephone Exchange. The Chamber of Commerce were negotiating with a view to such an arrangement when the Telephone Company stepped in and solved the difficulties by placing these offices on the Telephone Exchange without charge.

Institution of Electrical Engineers.—On Friday last Mr. Müller read his paper on "House Telephones" before the students of the Institution; General C. E. Webber in the chair. An interesting discussion followed, in which the Chairman, Messrs. Raphael, Horn, Bone, Foyster, and Cross took part. Mr. Stephens will read a Paper on "Marine Propulsion by Electricity" on the 23rd inst. This will be the last meeting of the students before the summer vacation.

Birkenhead.—A special meeting in committee of the Town Council was held on Monday afternoon, to take into consideration the alterations made by the Board of Trade in the Birkenhead Electric Lighting Provisional Order. The Town Clerk said there was scarcely a single clause which had not been altered in some way or other. After a lengthy discussion as to the advisability of proceeding with the Order in its altered form, it was decided, with only two dissentients, to go on with it.

A New Application of Electric Heating.—According to certain Italian journals the dome of St. Peter's is cracking in a somewhat serious manner. *La Lumière Electrique* states that a similar state of things was discovered about 100 years ago, and was remedied by encircling the dome with a strong band of metal. This band was heated, and its contraction on cooling was found to be sufficient to close up the fissures. Our con-

Digitized by Google

temporary suggests the use of electricity if a similar method should be tried in the present case.

The Shetland Cables.—Mr. Lyell asked the Postmaster-General on Monday whether he was aware that the telegraph cables between Mossbank and Ulsta, and between Yell and Uist, in Shetland, had both been broken for some time, thereby causing much inconvenience; and whether he would have these cables repaired without delay. Mr. Raikes, in reply, stated that the cable ship of the Post Office had gone into dock for certain necessary repairs, but he trusted she would be able to proceed to the Shetlands next week.

The Mexican Telegraph System.—In his message to Congress on April 1st, General Diaz stated that the telegraph system had been extended and improved, 938 kilometres of new lines having been constructed from September up to date. The federal telegraph lines had reached a total length of 23,000 kilometres, without counting the double and treble lines, which measure 6,200 kilometres. There were, he said, besides, 28,900 kilometres of telegraphs and telephones belonging to single States, private individuals and railways.

Fire at Messrs. Robey's Works.—Late on Tuesday night a fire occurred at the engineering works of Messrs. Robey and Co., Lincoln, where more than 1,100 hands are employed, and the flames were not subdued until an early hour on Wednesday morning. The fire broke out in the steam sawing and planing mills, and when discovered had obtained possession of the central portion of the building, at each end of which were drying sheds, in which were stored large quantities of timber. The damage estimated at nearly £8,000, is covered by insurance.

The Electric Light in the Suez Canal.—In his last report to the Foreign Office the British Consul at Port Said gives the following interesting figures with regard to the application of the electric light to vessels navigating the Suez Canal at night. In 1887 395 steamers used the light; in 1888 the number rose to 1,611, and in 1889 a total of 2,445 vessels navigated the canal with its aid. The average time of transit has been reduced to 22½ hours. The shortest time taken by a steamer in passing through the canal in 1889 with the aid of the light was 14¾ hours.

Telephone Rates in Switzerland.—Under a law recently passed by the Swiss Federal Council, an annual subscription entitles a telephone subscriber to 800 conversations, with a supplementary rate of 5 francs per 100 conversations. For interurban telephone systems the rates are: For a conversation of three minutes 30 centimes up to 50 kiloms., 50 centimes up to 100 kiloms., and 75 centimes for greater distances—all of which are calculated "as the crow flies." The new law appears to operate in a satisfactory manner, and the lowering of the charges has produced an appreciable increase in the receipts.

Damages to a Post Office Cable.—In the Queen's Bench on Tuesday, the case of the Attorney-General *v.* Taylor was an information by the Crown against the master of the "Olive Branch," for so negligently navigating his vessel as to damage a cable laid in the bed of the Medina River, Isle of Wight, and conveying messages to and from Osborne. It appeared that the anchor of the defendant's vessel caught in the cable and caused damage which cost £29 to repair. The defendant pleaded not guilty, and contended that the position of the cable was not sufficiently indicated by the buoys placed by the Postmaster-General. The jury took this view, and returned a verdict for the defendant.

Paddington Vestry.—At a meeting of this Vestry on the 6th inst., a communication was received from the Board of Trade with reference to the resolution of the Vestry discontinuing its opposition to the application of the Metropolitan Electric Supply Company for a Provisional Order, stating that, although the rules of the Board of Trade require that the consent of the Local Authority be given to an application for a Provisional Order at a special meeting, of which one month's notice had been given, they would be prepared, if the Vestry desired it, to proceed with the settlement of the Metropolitan Electric Supply Company's Order, pending the passing of the formal resolution. A motion of adjournment was carried by 17 to 10 votes

Siemens-Martins Compressed Steel Shafting.—Compressed polished shafting of a high quality not requiring turning is now being introduced in Germany by Reimbold, of Mettmann. These shafts are produced to exact diameter, perfectly round and straight. They are made of pure soft Siemens-Martins steel, 20 to 25 per cent. carbon, admitting of being welded and tempered. They have, it is said, 50 per cent. greater tenacity than ordinary shafts. From experiments made by Messrs. David Kirkaldy and Son, of London, it was shown that the limit of elasticity of these shafts was 79,200lb., that of ordinary iron being 23,800lb, and of patent rolled shafts 60,600lb. The relative strength therefore is—iron 1,000lb., rolled shafts 1,505lb., compressed polished shafts 1,612lb.

Edinburgh Chamber of Commerce and the Telephone System.—The Edinburgh Chamber of Commerce has forwarded a memorial to the Postmaster-General with reference to the acquisition of the telephone system by the Government. By acquiring the telephone system at the earliest possible date, the memorialists are of opinion that the Government will purchase proportionately much cheaper than in seven years hence, and that the telegraphic revenue, which, they say, is now suffering from telephonic communication, would be sustained and increased by the additional revenue arising from the extended telephonic system, and by economies which will arise from the two systems being operated in harmony. A similar memorial has been sent to the Lords Commissioners of Her Majesty's Treasury.

Church Lighting.—An interesting installation of the electric light is to be seen at the Holy Trinity Church, Sloane-street, Chelsea. The lighting arrangements have been planned and carried out by the Brush Electrical Engineering Company, in conjunction with Mr. J. D. Sedding, the architect of the building. The nave is lighted by five elaborate lanterns, fitted with 8 and 16 candle-power lamps. The morning chapel and aisles are supplied with lanterns of a less elaborate design, also fitted with a number of 8 and 16 candle-power lamps. The entrance lobbies, gallery stairs, corridors, vestries, musicians' galleries, and parish room are all lighted with groups of three and four lamps, arranged on artistic wrought-iron electroliers, designed and manufactured by the Brush Company. When completed the installation will consist of 130 16 candle-power incandescent lamps, and 103 8 candle-power ditto. The supply of current is derived from the mains of the Chelsea Electric Supply Company.

The Non-Conductivity of a Vacuum.—In a recent Paper in Wiedemann's *Annalen* on "The Electrical Conductivity of Gases," T. Homen denies the validity of Foeppl's so-called experimental proof of the non-conductivity of a vacuum described in Vol. XXXIII. of the *Annalen*, and of which an abstract was given in *The Electrician* of June 1, 1888. Homen points out that the length of path to be traversed by the discharge in Foeppl's experiment must have been at least 13 metres. Now, his own recent experiments show that in an electrical discharge through rarefied gas there is an addition to the true ohmic resistance, a resistance of the nature of a counter E.M.F., and for a length of path of 13 metres, and a pressure equivalent to 0·09 millimetre of mercury, the value of this counter E.M.F. would be about 5,200 volts, and at this pressure the counter E.M.F. diminished as the pressure increased, it would probably be greater for higher vacua. The E.M.F. of about 270 volts employed by Foeppl could not, therefore, be expected to produce a discharge.

Chinese Telegraph Convention.—In answer to Sir J. Lubbock, Sir J. Fergusson stated in the House of Commons, on Thursday last week, that the arrangement between the Chinese Government, the Northern Telegraph Company, and the Eastern Extension Company was signed on August 10, 1887, and purposed to provide for a fixed rate on through messages from Europe to China, by whatever route transmitted, until 1903. The Convention was, however, made subject to approval by the British and Russian Governments, and Her Majesty's Government have not given their consent to it, and the whole matter is for the present in abeyance. The consent of Her Majesty's Government would not be given to any agreement without full

Digitized by Google

consideration of all the interests involved and consultation with the representatives of British commerce.

Electricity on the Stage.—In the opera of "Ascanio" there is an interesting application of electricity to stage purposes. The lighting of the torch of Phœbus is effected by an incandescent lamp enclosed in red transparent framework representing flames; the lamp being supplied with current by a battery of accumulators contained in the handle. The accumulators are six in number, and are of the Planté type. The plates are 5 cms. high and 7 cms. broad and 1·5 mm. apart, and are rolled round one another. The active surface is about one square decimetre per cell. The cylindrical containing vessels are of thin glass, surrounded with gutta-percha. They are 7 cms. high by 2 cms. in diameter. The battery is divided into two groups arranged one above the other. The cells are all connected in series, and are capable of furnishing 3 amperes at an E.M.F. of 10 volts for 30 minutes.

Electric Lighting in St. George's, Hanover-square.—In answer to a question by Mr. Leveson-Gower, Sir M. Hicks-Beach stated in the House of Commons on Monday that he had been urged by the Vestry of St. George, Hanover-square, to grant a Provisional Order allowing a third company to supply electrical energy in the parish, in addition to the two companies, the London Electric Supply Corporation and the Westminster Electric Supply Corporation, already possessing such powers. He was not, however, prepared to interfere with the arrangements made in the metropolis last year, until the companies to whom powers were then granted had been allowed a reasonable time for proving their ability to discharge their obligations. He had, however, informed the companies in question that he should not be disposed to adopt this course another year unless they could prove that they were in a position to supply energy in the district.

Belgian Lightning Statistics.—According to some statistics published by the Société Belge des Électriciens, 229 lightning strokes were reported in Belgium during 1888, or more than double the number of the previous year. Three well-authenticated cases of globular lightning were reported. Near Antwerp, a well running along a ditch was struck by lightning, and a number of fish were killed by the flash; a military engineer stated that the water was turned a bluish tint, and gave off sulphurous fumes. The Château de Moulbaix, in Hainault, was struck by lightning and burnt down, the damages amounting to over half a-million francs. In only one instance was any damage done where there existed a lightning conductor erected in the manner laid down by the Académie des Sciences. The exception was the destruction of an anemometer at the Brussels Observatory, the instrument in question, however, being a long way from the conductor.

The International Telegraph Conference.—The following letter from Sir James Anderson appeared in *The Times* of Wednesday:—

"Sir: In your issue of the 10th inst. Mr. Meyer, of 16, Exchange-buildings, Liverpool, says that he is informed on good authority—first, that there is a proposal to be submitted to the Conference to reduce the limit from ten to eight letters in code language; and, second, that an authorised code of 100,000 words is to be issued. Neither of these propositions has been, to my knowledge, brought forward by any one of the States represented at the Conference, and the companies have never entertained such ideas. He next says that in 1886 I 'maintained that the public should be warned that, sooner or later, the present abused code system should be stopped.' What I really said was that 'the commercial public should be warned that, sooner or later, the present abuse of the code system will be stopped, to the great inconvenience of those firms who are building up a huge mass of made-up words, syllabic combinations having the appearance of words only, and unknown to any language. This practice, which is growing, is unfair, if not illegal, and contrary to the convention by which all telegraph administrations are bound, and will some day have an abrupt ending, especially if ever there is Government control of any kind.' As far as we know, there is no one thinking of interfering with the use of legitimate words which are to be found in the eight authorised languages."

The sittings of the Conference, which commence to-day, will be held in the Salle de Manège of the Louvre, and the opening meeting will be presided over by M. Jules Roche, Minister of Commerce.

The Central London Railway Bill.—The Select Committee of the House of Commons on the Central London Railway Bill sat on Tuesday for the purpose of going through the clauses of the Bill. The Committee passed a new clause, which provided that the frontagers should receive no compensation for the use of the subsoil, but should be compensated by the Company should any damage be done to cellars or other property by the removal of subsoil. The Chairman, after hearing a statement by Mr. Greathead, the engineer, to the effect that the City and Southwark line would be open to the public in a month or two, decided that no prospectus should be issued or capital raised until that line had been worked for a period of at least three months. Mr. Freeman then said that the County Council wished to insert a clause compelling them to set their stations back in a similar manner to Charing Cross. The Chairman said the Committee were of opinion that the clause proposed by the Council, by which they had power to require the promoters to set their stations back when necessary, was a reasonable one. Mr. Freeman said he was prepared to accept the clause provided the Council gave them notice as to which stations they wished set back. Mr. Cripps, on behalf of the Council, promised that due notice should be given within three months of the passing of the Bill.

Severe Thunderstorms.—During a severe thunderstorm last week Sanquhar Parish Church was struck by lightning. The northern spire was the point of impact, the electricity then passed through the belfry and tower to the western vestibule, and after destroying wainscoting, plaster, and gas pipes, blew down the right-hand door, and forced its way into the church. Here the discharge divided, one portion demolished a pew, and made its way to earth by blowing a stone right out of the thick wall close to the surface of the ground. The other portion apparently crossed the church, for many seats and portions of the ceiling were more or less damaged, and every window in the sacred edifice suffered, close on 200 panes of glass having been destroyed. The church and vestibule is said to present the appearance of a building that has undergone bombardment. —On Tuesday evening last week a severe thunderstorm broke over Preston, in the course of which three persons were struck by lightning.—On Wednesday last week Irvine was visited by a storm. About six o'clock the lightning struck Fern Bank House, in Bank-street, damaging the gable and chimney. One of the copestones on the roof of the house was thrown a distance of 20 yards.—On Thursday last week violent thunder storms broke over Wales. Two girls at a farm known as Pantgwyn were struck, and the upper portion of the house in which they were was partly wrecked. In Carnarvonshire a quarryman, working at the Nantyfron Quarries, Talysarn, was struck by lightning and killed.

The Destruction of Telegraph Insulators.—Insulators have long been considered by the public as proper objects on which to experiment in the ancient art of stone-throwing, and in Belgium it would seem that the peasants have a special predilection for this kind of sport. M. Emile Pierard, telegraph engineer to the Belgian Government, reports that owing to the great destruction of telegraph insulators it became necessary to employ some of an unbreakable nature. It was found, however, that these insulators, which were sunk in a protecting cover of galvanised iron, were both extremely heavy and extremely costly. Another system was, therefore, adopted. It was thought that the large white insulator generally employed naturally attracted the attention of individuals of a destructive turn of mind, and it was decided to experiment with one of a less obtrusive colour. The porcelain enamel was coloured a greyish brown by mixing a silicate with it. This process did not impair the insulation properties in any marked degree, and the colour of the posts being also a greyish brown, it was difficult to distinguish the insulator from its support. A line 22km. long was selected, and provided with 102 insulators of each kind, arranged alternately. In one year 25 of the ordinary white insulators were broken, but only 13 of the coloured ones. Taking into account the somewhat higher price of the coloured insulators, but not the cost of labour in replacing the broken insulators, these figures mean an economy of about 42 per cent. All broken white insulators are now replaced by brown ones, and if these are broken protected insulators are substituted.

MAGNETISM IN IRON AND OTHER METALS.*—XVII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from Vol. XXIV., page 643.*)

§ 73. **Curves of Permeability and Susceptibility.**—The behaviour of magnetic metals during the imposition of magnetic force is sometimes exhibited graphically in other ways. Instead of drawing a curve to show the relation of **B** or of **I** to **H**, as has been done in the examples which have been given, we may draw a curve showing the relation of κ or of μ to **H**. This method of representing the results of experiment was used by Stoletow.† Another, and better plan, due to Rowland,‡ is to represent μ in relation to **B**, or κ in relation to **I**. These may be called permeability curves and susceptibility curves respectively. The following are a few examples. :—

§ 74. **Susceptible Curves for Wrought-iron Wire.**—Fig. 40 shows two curves of κ and **I** for the experiment described above in § 66, where the same piece of wrought iron was tested, first in the soft annealed state, and again after being hardened by stretching. Curves μ and **B** would have the same form, since in wrought iron μ is almost exactly $4\pi\kappa$, and **B** is almost exactly 4π **I**.

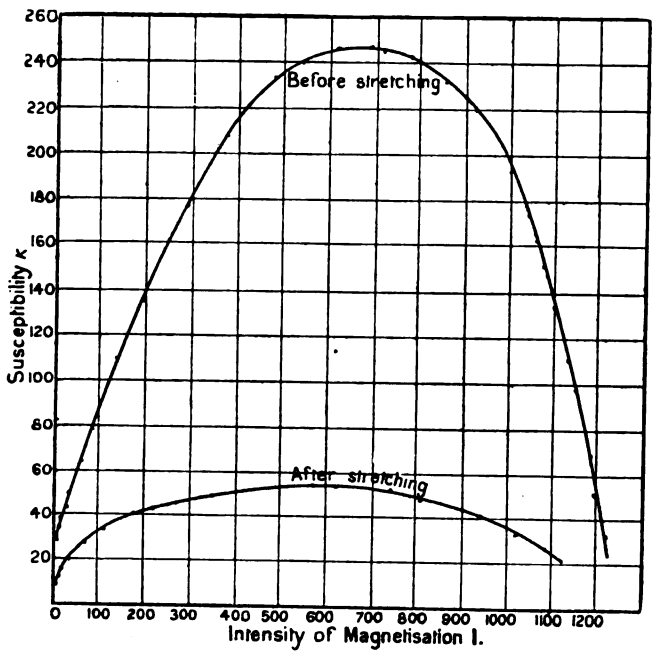

Fig. 40.—Relation of κ to **I** in iron before and after stretching.

The approximate symmetry which a curve of this type exhibits about an inclined straight line through the apex was noticed by Rowland, and led him to devise an empirical formula, from which, by extrapolation beyond the limits of experiment, a limiting or saturating value of **B** or of **I** might be deduced. It has, however, been shown by other observers, that when the magnetic force is sufficiently raised the curves cease to be even approximately symmetrical; the empirical formula then fails, and it is not possible by producing the curve beyond experimental values to find a limiting intensity of magnetisation. There is a true saturation value of **I** (not of **B**), as will be shown later; but it cannot be found in the manner suggested by Rowland, because the curve of κ and **I** or of μ or **B** bends out under high forces, becoming concave on its upper side. This feature will be seen below in the corresponding curves for nickel and cobalt.

§ 75. **Permeability Curves for Nickel.**—Fig. 41 gives three permeability curves for a nickel rod in the annealed state, tested within a yoke:—The lowest, shown by a full line, is the curve got when the rod was tested under ordinary conditions; the other two, shown by dotted lines, relate to tests made when the rod was subjected to compressive stress. An account will be given later of the effect of stress on the magnetic qualities of iron, nickel, and cobalt; meanwhile it may suffice to explain that nickel is extremely sensitive to stress, its susceptibility being greatly reduced by tensile stress, and greatly increasing by compressive stress. The upper and lower dotted curves relate to compressive stresses of 6·8 and 3·5 kilogrammes per sq. mm. respectively.

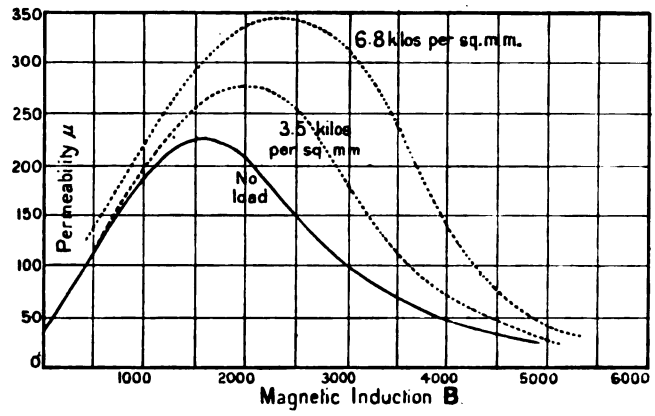

Fig. 41.—Permeability of nickel in the annealed state.

§ 76. **Permeability Curves for Cobalt.**—Fig. 42 shows in the same way two permeability curves for a rod of cast cobalt, tested in a yoke. In this experiment the rod was tested first under ordinary conditions of no stress, and then under a series of loads producing various amounts of compressive stress. The full line is the curve for no load; the dotted line is for a load of 16·2 kilogrammes per square millimetre. The curves cross, showing that under weak magnetic forces cobalt has its permeability increased by the presence of compressive stress; but under sufficiently strong forces the reverse is the case.* In a later chapter it will be shown that a similar reversal of the effects of stress occurs in iron.

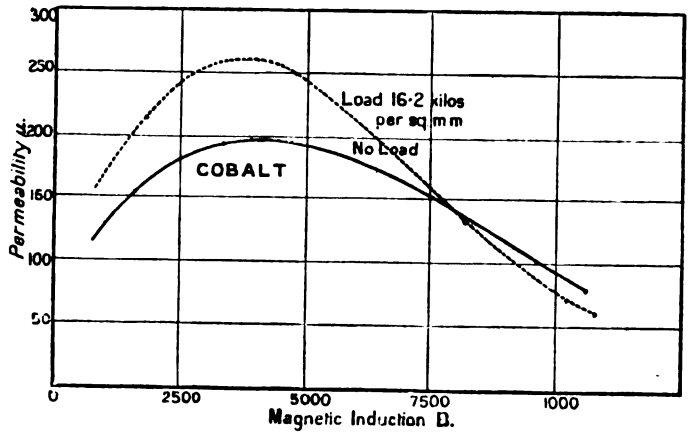

Fig. 42.—Permeability of cast cobalt.

§ 77. **Magnetic Hysteresis.**—The curves which have been drawn to show the effects of cyclic magnetising processes in iron, steel, nickel, and cobalt, have this important feature in common, that there is a tendency on the part of the metal to persist in any magnetic state which it may have acquired, which is exhibited whenever an alteration begins to be made in the character of the magnetising process. Thus, when the magnetising force has been raised to its highest value, we find, on beginning to reduce the force, that the magnetism tends to remain. It does

* All rights are reserved.

† *Phil. Mag.*, January, 1873.

‡ *Phil. Mag.*, August, 1873.

* In a Paper by Mr. C. Chree, published in abstract in *Proc. Roy. Soc.*, December 19th, 1889, the same conclusion is stated, along with other results of experiment on the influence of pressure on the magnetic qualities of cobalt. The experiments with cobalt described in the text, and illustrated in Figs. 39 and 42, were made in 1888 by the writer and Mr. W. Low They have not been previously published.

Digitized by Google

not all remain, but the rate at which it disappears during withdrawal of the magnetising force is notably less than the rate at which magnetism was being acquired duringimposition of the force, especially at the beginning of the withdrawal. The existence of residual magnetism when the force is wholly withdrawn is one result of this reluctance which the metal shows to change its magnetic condition. But the results of this tendency go further. If, for example, after withdrawing the magnetising force, we begin to re-apply it, we find in the early stages of the process the same reluctance to change; the metal begins to regain magnetism, but not so fast as it was losing magnetism during the last stages of the removal of the force. The rate, however, improves, and when the force has been completely restored we find that the piece has recovered all, or nearly all (sometimes even a little more than all), the magnetism it lost while the force was being withdrawn. The curve of magnetisation comes back to the same, or nearly the same, point as that from which it started; but its path during the process of return differs entirely from its path during removal of the force. The two curves form a loop, and any intermediate value of the magnetic force is associated with different values of the magnetisation during the two processes.

Moreover, this description applies equally to the effects of *any* cyclic variation of magnetic force, provided the range through which the force is varied be not exceedingly small. Starting from any condition of magnetism and of magnetising force, if we remove and re-apply a part of the force, or if we apply and remove a supplementary force, and repeat the process until its effects become cyclic, we find that the two stages of the process may be represented by two curves, which do not coincide, but differ in a way which may be concisely described by saying that there is a tendency, at each change of process, for the preceding magnetic condition to persist. The changes of magnetism lag behind the changes of force. This tendency has received the name of *magnetic hysterēsis*, from ὑστερέω, to lag behind.*

(To be continued.)

THE APPLICATION OF ELECTRICITY TO AGRICULTURE.†

BY N. SPECNEW.

Electricity has already been applied to numerous commercial purposes, and in this article I propose to study its influence on plants and its application to agricultural purposes. Ever since electricity has been a science its effect on the growth of plants has been the object of much research. The early investigations, however, resulted in contradictory results, which may be explained by the then imperfect state of electrical science, and by the embryonic conditions of its technical applications. It was owing to this state of affairs that Jolabert, Nollet, Mainbray, Achard, Berthollon, and Pardini Van-Marum, affirmed that electricity favoured the development of seeds and accelerated the growth of plants; whilst Ingenhouse, Van Trootswyck, Sylvestre, Senebier, and, to some extent, Decandolle, categorically denied the influence of electricity. The experiments of these *savants* were evidently inexact, and were carried out in a too limited manner; though, on examining them more closely, we find manifest indications of the influence of electricity. Gradually, however, scientific investigations established in a definite manner the incontestable fact that electricity had a beneficial effect on vegetation. To this result the works of Sir Humphry Davy, Bischoff, Humboldt, Wollaston, and especially Becquerel, largely contributed. But these scientists only occupied themselves with the theoretical side of the question; and it is only since 1845 that the first practical experiments in electro-culture have been undertaken. At this date, side-by-side with barren attempts to utilise gigantic electro-static machines, as suggested by Williamson, we hear of the application of a current of electricity produced by two metallic plates, one of zinc and one of copper, placed in the soil, and united by a wire. This method was first employed in England in 1846 by Sheppard, then by Forster in Scotland, and in 1847 Hubeck in Germany surrounded a whole field with a network of wires. Unfortunately, the results of these experiments were published in terms too vague to be of much use. Sheppard came to the conclusion that his experiments showed that electricity only increased the return from root plants, while grass perished when placed close to the electrode. He also asserted that one-third of the plants which developed were inferior to those which had been under the influence of the electric current. According to Hubeck, seeds developed more rapidly, and buckwheat gave a larger return; but in all other cases the electric current produced no result. At the same date the experiments of Prof. Fife were going on in England, and those of Otto von Ende in Germany. These experiments gave negative results, and even led these scientists to advise the complete abandonment of attempts to apply electricity to agriculture.

After a long interval of time we have the investigations of Fichtner, who employed a battery, the two wires of which were placed in the soil parallel to one another. Between these wires, and parallel to them, peas, grass, and barley were sown, and in every case the crop showed an increase of from 13 to 27 per cent. when compared with the ordinary methods of cultivation.

These experiments, and a number of others, led me to investigate the influence of electricity on plants in every state of their development; but I will content myself in this article with describing only those experiments of practical interest.

I. This experiment showed that by submitting different seeds to the action of an electric current their development is rendered more rapid and more complete. I employed in these experiments seeds of haricot beans, sunflowers, winter and spring rye. In every case twelve groups, containing 120 seeds each, were taken and submitted to the action of the current. Twelve exactly similar groups were not submitted to the action of the current, but, with this exception, were treated in identically the same manner. Both lots of seeds were first plunged into water until they swelled. The seeds were then submitted to the action of the current in the following manner:—When still wet they were introduced into long glass cylinders open at both ends. Two copper discs were introduced at either end, and were pushed in until they compressed the seeds. Rods attached to these copper discs were connected to the poles of an induction coil. The circuit contained an ammeter, and the current was kept on for one or two minutes; immediately afterwards the seeds were sown. The temperature was kept during the whole time that they were growing at 6° to 8° Réaumur (45° to 50° F.). These experiments were repeated ten times, and the results in the table below are most striking. I have also to add that the plants which resulted from the electrified seeds were more developed; their leaves were far larger and their colour brighter than in the case of plants resulting from the non-electrified seeds. The current had no effect on the yield.

——	Peas.	Beans.	Barley.	Sunflowers.
	Days.	Days.	Days.	Days.
Electrified seeds developed in	2·5	3	2	8·5
Non-electrified seeds developed in..	4	6	5	15

II. A second series of experiments was carried out with large plates (·445 metres × ·712 metres) of zinc and copper which were placed in the soil at the ends of the plots, the rods connected to their upper faces being united by a wire. This disposition was, therefore, equivalent to a battery (zinc | earth | copper), the current of which passed from one plate to the other through the ground. This method was applied more especially to pot herbs and flowering plants. The experiments were carried out at the Botanical Gardens at Kiew. The influence of the current was manifested by a larger crop and by the growth of vegetables of enormous dimensions.

* *Proc.* Roy. Soc., No. 216, 1881, p. 22; *Phil. Trans.*, 1885, p. 524.

Digitized by Google

III. In a third series of experiments the idea was to apply electricity on a large scale, and current electricity was replaced by static electricity. These experiments were carried out on a site situated in the Government of Pskow. In order to understand them better, it is necessary to remember the effect which has been established by experiments, viz., that the slow discharge of static electricity facilitates the assimilation of nitrogen by plants. It is for this reason that plants which are grown in a Faraday metallic cage contain 50 per cent. less organic matter than the plants which are grown in the open air.

On the different plots of earth sown with different seeds (see table below) we placed insulating rods, at the top of which were placed collectors, shaped like crowns. All these collectors were united by means of wires. Atmospheric electricity was thus collected above the seeds, and they matured in the midst of a highly electrified atmosphere. The results of this form of electro-culture are shown in the table. The figures give the averages of five years. All the plots between which comparisons are made were under identical conditions. These figures show, indisputably, that there is a considerable increase in the yield, whether of seed or straw; it was also observed that ripening was more rapid, especially for barley, which, in many instances, ripened twelve days sooner with electro-culture. Another important phenomenon was also observed. Potatoes were seldom diseased when grown by electro-culture; instead of 10 to 40 per cent. of them being bad, only 0 to 5 per cent. were so. These properties of electricity deserve all the more attention, since there are experiments which prove the beneficial effects of electricity on vines attacked by phylloxera. The enormous importance of these facts is self-evident; they seem to offer a new means of combating the microscopic diseases which attack vegetable growth.

A very practical question is—How much does electro-culture cost? I am only able to give the cost of experiments undertaken by myself. The cost of the two metallic plates in Experiment II. is about 16s. The installation of these plates does not require much time nor much technical knowledge, and it must be remembered that once *in situ* the plates are good for several years. The electro-static experiment No. III. was more costly, since it was necessary to have from 50 to 60 insulated rods per dessatin (2 acres). Each collector costs about 8s. But in this case also the expense once incurred the installation lasts for some time. I trust these experiments will be repeated on a still larger scale, and that some day we shall see electro-culture assume large proportions.

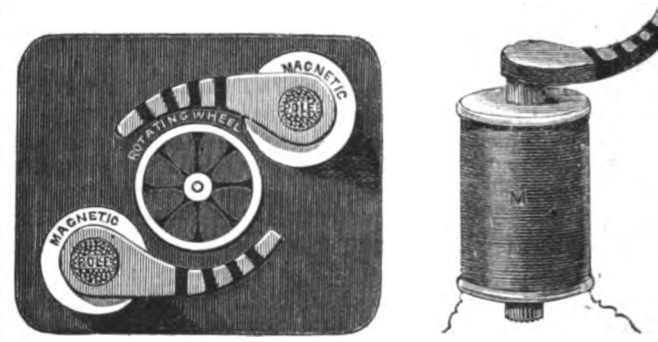
NOTE.—1 funt = ·9 lb.; 1 dessatin = 2 acres (approximately).

Thomson-Houston Electric Railways.—The following figures with regard to the Thomson-Houston Electric Company's traction work may be of interest. Up to April 1, 1890, this Company had 61 roads in operation, with 665 cars and 463·56 miles of track. They have under contract 39 roads, with 431 cars and 385·20 miles of track. The total is:—100 roads, 1,096 cars, 848·76 miles of track.

THE WRIGHT-FERRANTI ALTERNATE-CURRENT METER.

We give this week a brief illustrated description of an ingenious form of alternate-current meter which has recently been devised by Messrs. Arthur Wright and S. Z. de Ferranti. The meter was described by Dr. Fleming at the end of his interesting lecture at the Society of Arts, on Wednesday evening, and it forms a beautiful practical application of the principles underlying Prof. Elihu Thomson's remarkable experiments.

In the accompanying figures we have a rough diagrammatic representation of this meter. It consists in its latest form of a pair of vertical electro-magnets, the magnets having divided iron cores. To the poles of these magnets are attached curved horns of divided iron which lie in a horizontal plane. These curved horns are magnetically throttled at intervals along their length with copper bands. The curved horns embrace a circular space in which can revolve a light copper or iron shallow cylinder of thin metal. This cylindrical band forms the periphery of a light wheel capable of rotation on a vertical axis. Geared to this axis is a counting mechanism. The axis also carries a vane having mica blades.



The Wright-Ferranti Alternate-Current Meter.

The electro-magnetic principle, said Dr. Fleming, may be briefly described thus: The throttling of the curved iron horns causes the rapidly reversed magnetism to take the form of a lateral diffusion of lines of force from the sides of the horns. In effect a series of oppositely-named magnetic poles travels along the horn from the base, where it is in contact with the top of the electro-magnet, to the tip. These poles are represented by a series of bunches of lines of force, setting out laterally from the sides of the horn, and travelling up it. The lateral passage of these lines of force through the metal band which forms the rim of the movable wheel generates in it eddy currents. These are continually repelled by the moving field producing them, and hence a motion of rotation is given to the wheel by the alternating magnetism of the magnetic poles.

The speed of rotation, being retarded suitably by the vanes, can be made to be proportional to the current strength of the current exciting the magnets, and hence the total turns of the wheel in a given time to the total electric quantity flowing through the meter.

ON PROF. ELIHU THOMSON'S ELECTRO-MAGNETIC INDUCTION EXPERIMENTS.*

By J. A. FLEMING, M.A., D.Sc., M.I.E.E., Professor of Electrical Engineering in University College, London.

I. In the Paris Exhibition of 1889, and in the United States Court, many present will, perhaps, recollect to have seen a collection of electrical apparatus, contributed by Prof. Elihu Thomson as his private exhibit. These pieces of experimental apparatus constituted the appliances for illustrating some highly remarkable and interesting facts in electro-magnetic induction. It is more than probable that very many persons interested in electrical discovery either did not find, or did not happen to see in action, these instruments, or perhaps had not the opportunity to see them at all.

* A Paper read before the Society of Arts, May 14, 1890.

Digitized by Google

By the kindness of Prof. Elihu Thomson, to whom I am indebted for the loan of the apparatus, it is in my power to repeat some of these experiments before you to-night; and my obligations are likewise especially due to Mr. Ernst Thurnauer, the engineer of the European Thomson-Houston Electric Light Company, for affording me his valuable aid in bringing them before you, and to Mr. Garfield, of the Thomson Electric Welding Company, for assisting me in the preparation of the experiments. A few introductory remarks will be essential, in order that I may carry the whole of my audience with me in subsequent explanations; and these remarks will refer to that which is so very familiar a subject to every electrician, viz., the mutual induction of electric circuits. Before me lies a very large bobbin, or spool, wound over with two insulated copper wires. These wires were wound on the spool together, and for convenience sake we will distinguish them by calling them A and B (*see* Fig. 1). Bear in mind that the wires or circuits are insulated from each other throughout their entire length, but lie closely adjacent on the bobbin. I can at pleasure insert a large bundle of soft iron wires tied up together into the hollow split brass tube which forms the body of the spool. The ends of one wire, say A, are connected to the terminals of a glow lamp, and I can pass or interrupt an electric current which traverses the other circuit, B, and a second glow lamp in series with it. You will note at once what happens when I start or stop the electric current in the circuit B. The lamp connected to circuit A flashes up momentarily at the instant when the current *begins* to flow in circuit B, and also when it *ceases* to flow; but whilst the current flows steadily in the circuit B and illuminates the lamp in series with it, the lamp in series with circuit A is not illuminated at all. We have here a lecture experiment illustrating the familiar classical discovery of Faraday of the mutual induction of two electric circuits, viz., that the starting or stopping of an electric current in one circuit induces at the instant of commencement or cessation a brief secondary current in another closed adjacent circuit. I shall not take up time by dwelling on the historical details of this fundamental fact. You know them well.

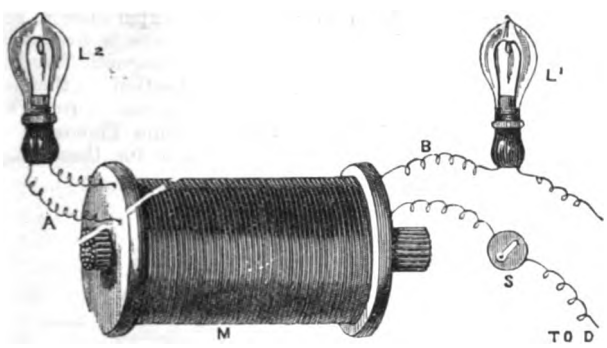


FIG. 1.

If instead of starting and stopping a continuously flowing electric current through the circuit B, and observing at each "make" or "break" a brief secondary current in circuit A, we supply the circuit B with an *alternating* electric current, one of which the direction is rapidly reversed many times in a second, and connect as before a glow lamp in series with circuit A, we find that this lamp glows continuously whilst the alternating current flows in circuit B. This also is familiar to us all. If in our first experiment we had employed, as a current detector in the secondary circuit, not an incandescent lamp, but some kind of galvanometer capable of indicating the direction of the induced electric current, we could easily have established for ourselves the fact that at the instant when the continuous electric current *begins* to flow in the circuit B it generates an oppositely directed induced secondary current in the circuit A, which is merely a transient current. At the instant when the continuous current is interrupted in circuit B it gives rise to a similarly directed transient induced electric current in the circuit A. These momentary currents in A are called the *inverse* and *direct* secondary currents, induced by the commencement or cessation of the continuous primary current in circuit B. If the primary current is rapidly reversed, as in the case of an alternating current, then the secondary current consists likewise of a rapid succession of currents alternating in direction. In most of our experiments this evening we shall employ an alternating current having a "frequency" of 90 per second—that is to say, changed in direction in the circuit 180 times in a second—and provided for us by the kindness of the London Electric Supply Company. If such an alternating current traverses a primary circuit it induces a secondary alternating current of the same frequency in an adjacent secondary circuit, and this secondary periodic current may be made to induce in another circuit a tertiary current of like frequency, and this again a quaternary current, and so on; these successive orders of induced currents being, as it were, the children, grandchildren and great-grandchildren of the primary parent current to which they owe their birth (*see* Fig. 2).

The same large spool of insulated wire will provide us with the means of illustrating another important fact. I join up the two wires A and B into one length, so as to form one continuous bobbin of wire, and connect this great spiral of wire with a couple of glow lamps, one being in series with the wire spiral, and the other being in parallel with it (*see* Fig. 3). On sending a steady current through the system, it divides between the wire spiral S and the lamp L_1, and I adjust the strength of this current so that the lamp L_1 is barely visibly red-hot. On interrupting suddenly this electric current, the lamp L_1 flashes up for a moment. We recognise that we have here to consider an inertia effect familiar to us as the effect of the "self-induction" in the long coil of wire. Audiences in this room have

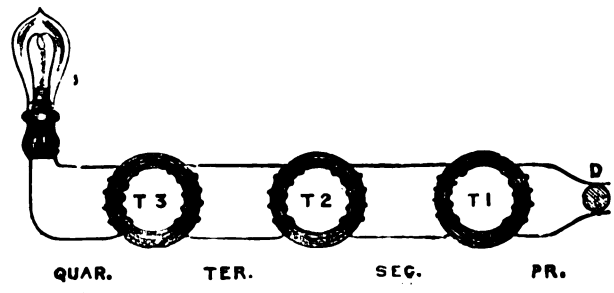

FIG. 2

been so carefully informed on many past occasions by brilliant and capable teachers that I may spare you a reiteration of elementary facts concerning the self-induction or inductance of conducting circuits, and take it for granted that everyone here is intimately acquainted with them, and that you will recall to your recollection that when an electromotive force acts upon any closed electric circuit generating in it an electric current, this self-induction exhibits itself by delaying or retarding the rise of the current strength to its full or its maximum value; and that, similarly, when the electromotive force is withdrawn, it operates to give the current a persistence or to retard the rate of reduction of the current strength. The convenient term "time-constant" of a circuit is employed to denote that time, expressed in fractions of a second or any other unit, which must elapse before a current rises to a certain definite fraction of its full value, when a steady electromotive force acts upon that circuit. I will next beg you to turn a

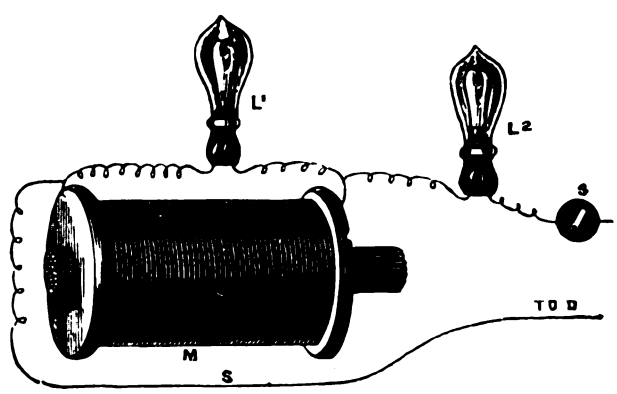

FIG. 3.

moment's attention to the electro-dynamic actions or forces which are brought into play when a circuit of any kind is subjected to electro-magnetic induction in a magnetic field. Consider, for instance, a ring of copper hanging in front of the pole of an electro-magnet (*see* Fig. 4) having the plane of the ring perpendicular to the lines of magnetic force proceeding out from the pole. Let the magnet be an electro-magnet, and let the pole be suddenly made a north or marked pole. Lines of magnetic force are thrust into the aperture of the ring. This magnetic flux, in accordance with a well-known law, generates an inductive electromotive force which causes a transient current to flow round the ring in a counter-clockwise direction, as looked at *from* the north magnetic pole. The ring becomes virtually a *magnetic shell*, having a north pole facing the north pole of the exciting magnet. By the fundamental laws of action, between currents and magnets established by Ampère, the ring experiences a slight repulsive force, due to the electro-dynamic

Digitized by Google

action between the current in the ring and the magnetic pole. The generation of the momentary induced current in the ring is accompanied by an electro-dynamic impulse tending to thrust it away from the pole. Suppose, next, that the electro-magnet is demagnetised. The ring has generated in it a reverse induced current flowing in the same direction as the hands of a clock move when looked at from the magnetic pole. This is also accompanied by an electro-dynamic attraction of the ring towards the pole, but which is much more feeble than the previous repulsion. These attractions and repulsions are well seen when small disks of copper or aluminium are suspended in front of the poles of a powerful electro-magnet, which is alternately "made" and "broken." They have been particularly investigated by Mr. C. V. Boys.*

I will now ask you to consider what would happen if the coils of the electro-magnet were traversed by an alternating current? Furthermore, we shall first suppose that the copper ring has a zero time-constant; that is to say, the induced currents

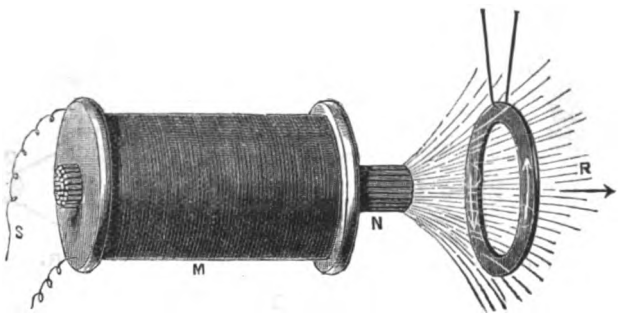

Fig. 4.

in the ring rise up and sink down in strength in exact synchronism with the changes in the inductive electromotive force acting on the ring. If the current flowing in the coils of the electro-magnet is represented as to changes in strength by a simple periodic curve, we may suppose that the magnetism of the core and the magnetic induction through the ring follow a similar law. It is very easy, then, to show that the induced electromotive force acting in the ring circuit, and hence the current in the ring, follows a similar law of fluctuation, but that the instant of maximum current in the ring coincides with the instant of reversal of magnetism in the electro-magnet. Under these circumstances we can represent the changing strength of the magnetic field in which the ring is immersed by a simple periodic curve m, and the changes of current strength in the ring circuit by another simple periodic curve c, shifted backwards relatively to the first by a quarter of a wave length (*see* Fig. 5).

By Ampère's law the force acting on the ring at any instant is proportional to the product of instantaneous value of the surrounding field and this current strength. If we multiply together the ordinates of these two curves m and c, and form a third curve p, whose

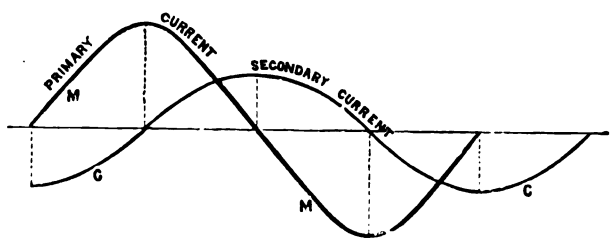

Fig. 5.

ordinate at every point is proportional to the product of the ordinates of the other curves (*see* Fig. 6) at those points, we obtain a curve which represents the fluctuation of force at every instant acting upon the ring. This curve p is also a wave-like curve, lying symmetrically above and below the horizontal line. The positive and negative areas of this curve included between the curve and the horizontal line represent the impulses or time integrals of the forces which act upon the ring. These impulses are alternately positive and negative. This is equivalent to saying that under the circumstances assumed the ring gets a series of small pushes and pulls, or repulsions and attractions, which succeed each other at the same rate as the changes of magnetic polarity of the magnet. The series of rapidly alternating and equal impulses would result in leaving the ring apparently unmoved. No real conducting ring can, however, behave in this fashion, because every real ring has a sensible "time-constant." Let us next see how the above state-

* On a "Magneto-Electric Phenomenon," By C. V. Boys, F.R.S. *Proc. Phys. Soc., London*, Vol. VI., p. 218.

ments will be modified if the ring has such a sensible self-induction that the current induced in the ring lags behind the inducing electromotive force in phase. Repeating the above construction for a force curve, on the assumption that the instant of maximum of the current in the ring occurs later than the instant of reversal of magnetism in the magnet, it is easy to see that the force curve consists now of two very unequal parts. It is not symmetrically situated with respect to the horizontal lines (*see* Fig. 7). The area of the hummocks (shaded portions) which lie above the datum line and which represent the repulsive impulses on the ring are much larger than the area of the hummocks below the datum line and which represent the attractive impulses acting on the ring. This means to say, that the ring when possessing self-induction experiences on the whole a repulsive force, or a series of repulsive impulses, when immersed in such an alternating magnetic field radiated from a

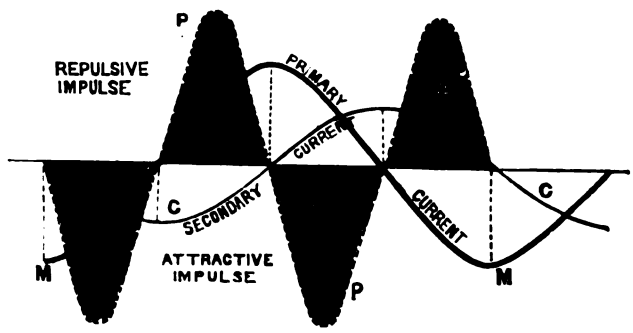

Fig. 6.

magnetic pole; and this repulsive force will be, within certain limits, more pronounced, other things being equal, the greater the time-constant of the circuit. You see clearly, therefore, that a ring or disc of copper in which the induced currents lag behind the inducing electromotive force in phase must experience a repulsive force when this inducing electromotive force is caused by a rapid flux backwards and forwards of lines of magnetic forces perforating through the ring or disc. The realisation of this inference in a striking manner is the first of a series of remarkable experiments on this subject due to Prof. Elihu Thomson. We have on the table an electro-magnet suitable for these experi-

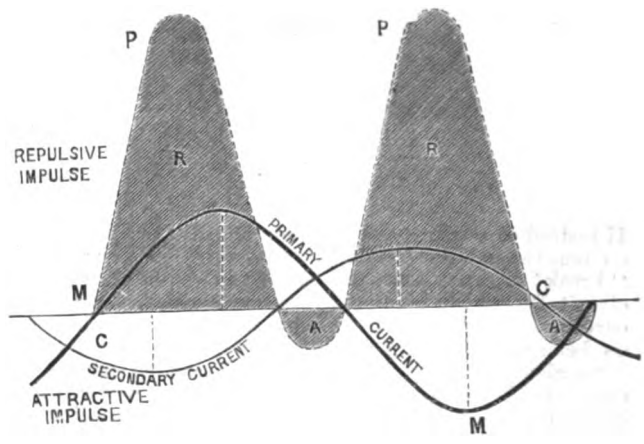

Fig. 7.

ments, which consists of a core of divided iron, surrounded by a coil in which I can cause to circulate a powerful alternating current of 40 to 50 amperes. Let us, however, begin with an experiment in which we employ a continuous current to energise the core. I give you, in Prof. Elihu Thomson's own words,* an account of this preliminary experiment: —

"In 1884, while preparing for the International Electrical Exhibition at Philadelphia, we had occasion to construct a large electro-magnet, the cores of which were about 6in. in diameter and about 20in. long. They were made of bundles of iron rod about $\frac{1}{16}$in. in diameter. When complete the magnet was energised by a current from a continuous-current dynamo, and it exhibited the usual powerful magnetic effects. It was found also that a disc of sheet copper of about $\frac{1}{16}$in. in thickness and 10in. in diameter, if dropped

Digitized by Google

flat against a pole of the magnet, would settle down softly upon it, being retarded by the development of currents in the disc, due to its movement in a strong magnetic field, and which currents were of opposite direction to those in the coils of the magnet. In fact, it was impossible to strike the magnet pole a sharp blow with the disc, even when the attempt was made by holding one edge of the disc in the hand and bringing it down forcibly towards the magnet. In attempting to raise the disc quickly off the pole a similar but opposite action of resistance to movement took place, showing the development of currents in the same direction as those in the coils of the magnet, and which currents, of course, would cause attraction as a result. The experiment could be tried in another way. Holding the sheet of copper by one edge, just over the magnet pole (*see* Fig. 8), the current in the magnet coils was cut off by shunting them. There was felt an attraction of the disc, or a dip towards the pole. The current was then put on by opening the shunting switch, and a repulsive action or lift of the disc was felt. The actions just described are what would be expected in such a case, for when attraction took place currents had been induced in the disc in the same direction as those in the magnet coils beneath it, and when repulsion took place the induced current in the disc was of opposite character or direction to that in the coils. Now let us imagine the current in the magnet coils to be not only cut off, but reversed back and forth. For the reasons just given we find that the disc is attracted and repelled alternately; for, whenever the currents induced in it are of the same direction with those in the inducing or magnet coil, attraction will ensue, and when they are opposite in direction, repulsion will be produced. Moreover, the repulsion will be produced when the current in the magnet coil is rising to a maximum in either direction, and attraction will

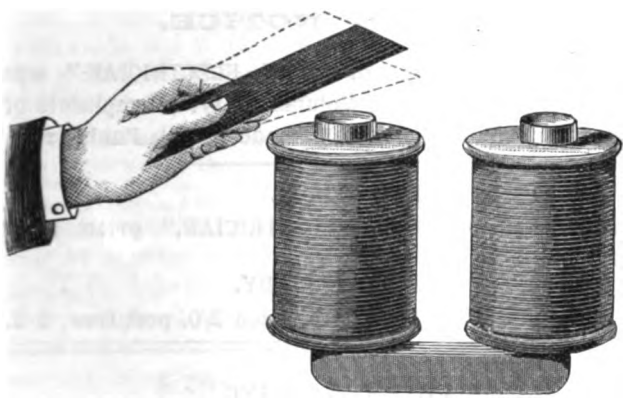

Fig. 8.

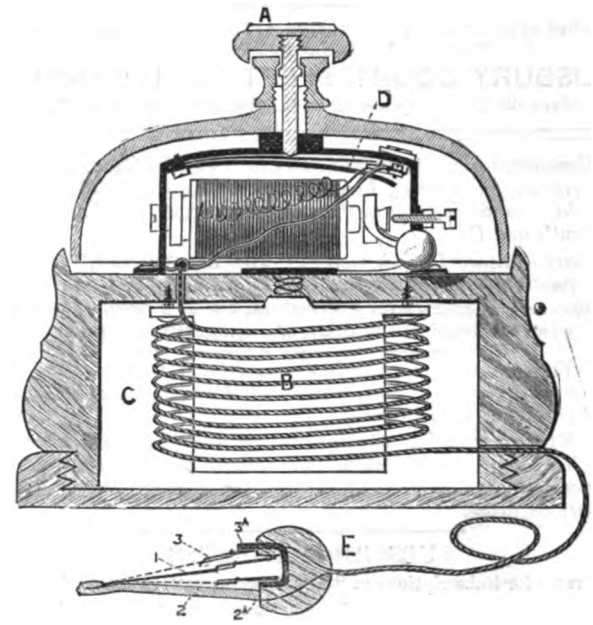
be the result when the current of either direction is falling to zero, since in the former case opposite currents are induced in the disc, in accordance with well-known laws; and in the latter case currents of the same direction will exist in the disc and the magnet coil. The disc might, of course, be replaced by a ring of copper or other good conductor, or by a closed coil of bare or insulated wire, or by a series of discs, rings or coils superposed, and the results would be the same."

(To be continued.)

PORTABLE ELECTRIC COMBINATION BELL.

The accompanying illustration is a section of an ingenious combined burglar and fire alarm, invalids' bell set and table call bell. The whole apparatus occupies no greater space than 3½ inches, and as the battery is a dry one it can be safely packed in portmanteau or travelling bag.

To use the apparatus as a burglar alarm, it is only necessary to detach the bottom of the case, uncoil the silk wire conductor C, and fix the contact press E to the door or window requiring protection, which, on being opened, will immediately start the alarm by releasing the spring, which flies back and makes contact at the *outer* projection 3A, the sliding tongue having previously been pushed back along the spring. The fire alarm can be adjusted to ring at any required degree above the normal temperature, and is constantly set. To enable a patient to communicate with another room, the contact press E, and as much of the cord as may be required, is taken out, and by pressing the spring, contact is made at 2A, and the bell rings. When in use as an ordinary call bell, the apparatus is placed on the table and the bell is rung by pressing the button A.



A, press for use as table bell; B, battery; C, flexible cord; D, fire alarm; E, double contact press, with sliding tongue on spring arm. 1, position when not in use; 2, making contact at 2A, for use as an ordinary press; 3, sliding tongue pushed back, allowing spring arm to fly up and make contact at 3A, for use as thief detector.

This compact little appliance is made by Messrs. E. J. Tumber and Co., of 4, Great Winchester-street, E.C.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, May 16th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: "On Huygen's Gearing in Illustration of Electric Induction." By Lord RAYLEIGH, F.R.S. "Dr. R. König's Researches on the Physical Basis of Music." By Prof. SILVANUS THOMPSON, D.Sc.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Photographic Image." By Professor RAPHAEL MELDOLA, F.R.S.

TUESDAY, May 20th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "The Keswick Water-Power Electric Light Station." By Messrs. FAWCUS and COWAN, Assoc. MM. Inst. C.E.

WEDNESDAY, May 21st.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and to be crossed* "*Coutts and Co.*"

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The Directory was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

ELECTRIC TANNING.

For some years past the use of electricity as an agent for facilitating the processes of tanning has been progressing, through the usual stages of experiment and apparent failure, toward sound and practical success; though it is only quite recently that really solid results seem to have been attained. In this particular field of industrial application progress has been the more difficult because, of all the branches of applied chemistry, the art of tanning is, perhaps, the most empirical. The processes of the tanner are, for the most part, mere rule-of-thumb methods, to which little has been added for a century, save in the increased use of astringents prepared from foreign barks, such as mimosa and chestnut, as compared with the time-honoured use of astringents prepared from the bark of the oak. Raw hides are still fleshed, unhaired, and limed in accordance with ancient custom, and steeped for months in pits, the duration of the process depending on the nature and thickness of the hide and the quality of leather to be produced. All processes which take so long a time as from six to ten months for their completion are naturally carried on at a commercial disadvantage when compared with processes that can attain the same result in a shorter time. A greater capital is involved for an equal weekly output, and the fluctuations of price as between the raw materials and the finished product cannot be turned to advantage, if the process which transmutes the former into the latter requires many months, so readily as is the case if the process occupies but a few days. Hence, there

Digitized by Google

have been many attempts to reduce the time required for tanning by the use of stronger extracts and astringents than the ordinary tan liquors. Most, if not all, of such processes have been condemned by the light of experience, as the leather produced rapidly by such means will not stand the test of wear or strain. The reason is simple. In the ordinary steeping processes of the tan-pit the hide is immersed in liquor which, as fast as it tans the surface, by that very fact renders the surface less permeable to the penetration of the liquor into the inner parts; hence the outer layers of the hide become tanned before the interior. This can readily be seen by taking a hide when but half tanned from the pit, and examining a section, when it will be seen that the middle of the section is still fleshy and whiteish, when already the exterior has become of the characteristic brown tint. This action is exaggerated when strong extracts are used in the pits, the exterior parts becoming over-tanned before the interior is half-tanned; brittle leather being the result. In face of the failure hitherto of all purely chemical modes of shortening the tanning process, it is not strange that throughout the entire tanning industry there should exist a violent prejudice against all rapid processes of whatever kind. But it is clear, from what has been said as to the cause of the failure of rapid processes, that if a means could be found to cause the tanning action to proceed simultaneously through all the layers of the hide at once, instead of attacking the outside first, and the inside afterwards, one of the strongest objections to the hastening of the process would have been removed.

As we understand it, this is indeed what is claimed to have been accomplished by the application of electric currents to the hides whilst they are being subjected to the action of the tan liquors. The notion is not altogether new. Various attempts have been made from time to time to apply electricity to tanning, amongst which that of the late M. Lucien Gaulard deserves some notice. In Gaulard's process the hide was placed in liquor between two parallel carbon plates, from one of which an electric current flowed to the other, the current being supplied from a continuous current dynamo machine. Skins stated to have been so tanned were, indeed, exhibited in England by Gaulard in 1888; but nothing came of the process, and it cannot be said to have proved successful.

In 1887, Messieurs Worms and Balé devised a process which differed in an important manner from that of Gaulard, inasmuch as another factor in the problem was introduced. It had been known in the tanning industry that if the hides, instead of hanging inert in the tan-pits, were subjected to mechanical motion, the penetration of the tan-liquor into the pores was facilitated; and some tanners had gone so far as even to place the hides and liquor in vessels to which motion was continuously imparted by machinery. This, of itself, to some extent accelerates the tanning action. The happy thought struck Worms and Balé that a combination of the two methods might give useful results. Accordingly, they devised apparatus for the simultaneous application of electricity and of mechanical movement, with results which far surpassed anything previously attained. Works were established near Paris which for eighteen months were in active operation, and then were removed into the city. Early last year a Company was formed in London to take up the Worms and Balé patents, under the name of the British Tanning Company; and during the time that has elapsed it has been steadily putting together the requisite plant for producing a large weekly output of leather. The Bermondsey works of the Company have this week been inspected by a considerable number of visitors. In these works the arrangements adopted are as follows: The raw hides are placed in large drums 11ft. 6in. in diameter, mounted so as to be capable of rotation, and fitted with internal electrodes to which connection is made through the bearings to a continuous-current dynamo machine. Each drum holds, as its charge, about half a ton of hides, and from two to two and a-half tons of liquor, the space inside the drum being about half filled. It is then set into slow regular rotation, and a current of electricity of about ten amperes is passed through it. The current is allowed to flow for a certain time and then cut off. The rotation is maintained for a time, which varies from two to six days, according to the thickness of the hides, which at the end of that time are found to be completely tanned, and are ready for the final currying processes. The liquor consists of an ordinary tanning extract, diluted to the required degree, to which a small percentage of oil of turpentine is added. It appears to be an open question as to which of the agencies employed the remarkable gain in time is due, no one of the means employed being alone able to produce the results. That the very small current density employed can so affect the molecular properties of the liquid as to enable it to penetrate the pores of the hides as rapidly as it does is a matter difficult to understand, and certainly cannot account for the whole of the results obtained. Neither can they be accounted for by the supposition that the electrolytic action of the current creates ozone or peroxide of hydrogen in quantities sufficient to alter the chemical operations to any great extent. Indeed, the part played by electricity in the process is still obscure. This much appears to be certain, that the tanning action goes on not at the surface only, but all through the substance of the hides at once; sections taken when the process is half complete showing no internal line of demarcation.

Another variety of tanning process, in which the hides are placed on rotating frames in a stationary vessel, through which electric currents are passed, has been patented by Mr. Groth, a former agent of the Worms and Balé process. As judicial proceedings are pending against Mr. Groth for infringement of legal rights, nothing can be said as to the relative merits of his process. In Sweden another electric tanning process has been at work for nearly two years in Nielson's tannery at Norrköping. The inventors of this process, Messrs. Landin and Abom, place the hides on wooden frames in a pit, with large copper electrodes at the sides; and they employ alternating currents of electricity. Their process, however, occupies forty-five days. It is claimed both for the Swedish leather and for that tanned in France and England by the more rapid process of Worms and Balé, that it is actually stronger than leather tanned by the old processes, and that there is a larger resultant weight of leather from a given weight of hides. With respect to the former point some statistics have been shown to us by Mr. Falkenstein, the manager of the Bermondsey Works, according to which the electrically tanned strap leather stands a tensile stress before breaking equivalent on the average to 4,305lb. per square inch; whereas strap leather tanned in the ordinary way gives on the average, according to the tests made by Kircaldy, only 3,572lb. per square inch. These figures point to a probable field of special usefulness for the electrically tanned leather for belting and other purposes where tensile stresses are to be transmitted. Whatever the merits of the individual processes, and whatever the ultimate scientific *rationale* of the facts may be, there seems now to be no question that electric tanning has got far beyond the experimental stage, and may be fairly included amongst the now numerous industrial applications of electricity.

ON LIGHTNING-GUARDS FOR TELEGRAPHIC PURPOSES, AND ON THE PROTECTION OF CABLES FROM LIGHTNING,

With Observations on the Effect of Conducting Enclosures.*

BY DR. OLIVER J. LODGE, F.R.S.

In the Paper which I read before the Institution last year I spoke at length and showed some experiments on the subject of the protection of buildings from lightning; but although there were a few sections in that Paper, as ultimately printed, dealing with lightning protectors for telegraphic instruments and cables, yet time prevented my calling attention to this portion of the subject at the meeting, or of showing any experiments in connection with it.

The present communication may be regarded as a development of this omitted but important branch of the subject.

I do not know whether I shall escape controversy this time, but I have no wish to provoke it; and I wish entirely to avoid decrying the merits of other specific protectors in order to emphasise the advantages of my own. All I have to say on this head will have a quite general application, and amounts to about this: that whereas all protectors proceed on the admitted fact that the greater portion of a sudden flash prefers to jump an air space, rather than traverse a moderate length of wire, the cause of this well-known fact was but imperfectly appreciated—could not, indeed, be perfectly appreciated without recognising the rapid oscillatory character of sudden discharges, and the doctrine of impedance, or immense obstruction which good conducting wires offer to currents of this character; an impedance, it may be, of 100 or 1,000 ohms, whereas the resistance to steady currents may be but a ten-thousandth part of this amount.

In a word, the complete theory of lightning protectors has not till recently been known, and accordingly the many ingenious devices which are in use are naturally deficient in details which a completer recognition of theory would have suggested.

Long ago it was shown by the experiments of M. Guillemin and Prof. Hughes that existing lightning protectors were not perfect safeguards, inasmuch as they could not protect a fine wire from deflagration by a Leyden jar discharge. At the same time it was admitted by these experimenters, and is, I understand, a matter of common experience, that almost any lightning protector is better than none at all, and that the best of those in use are by no means inefficient instruments. They do not afford perfect security, but the occasions when they partially fail are perhaps not very numerous. It is, therefore, the practice to establish some sort of proportion between the elaborateness of the protector and the value of the apparatus to be guarded. In telephone exchanges a simple double comb is used. In telegraph offices a pair of plates finely adjusted close together is the form employed, while at cable stations the most elaborate kind of protectors, and often a number of different ones in combination, are arranged, because of the enormous interests at stake.

In electric light installations, on the other hand, it is customary, I believe, at present to use no protector at all. But I cannot suppose that this will much longer be regarded as a reasonable procedure. When one considers the extensive ramifications of conducting leads which are rapidly growing up, and the liability of the neighbourhood of house lightning-conductors to some portion of such ramification, it is apparent, I think, that lightning arresters are just as important for electric light leads as for telegraph wires. However, there is no need for me to emphasise this assertion, for I expect that before long a flash from somebody's lightning conductor getting into some electric light leads and burrowing underground throughout a district will do an amount of damage sufficient to eloquently call attention to the danger. At Peterhouse, Cambridge, lightning got at the gas engine, thence to the dynamo, and thence into the leads; where, I believe, it did little more than fuse a large number of cut-outs. But it is not likely always to spare the lamps in so considerate a manner; while danger of an altogether more disastrous kind can by no means be considered absent.

Returning from this digression to the telegraphic protectors at present in use, my contention is that, in all except the very simplest and crudest form of protector, a perception of the true conditions may lead to more complete protection without necessarily much increase in cost. And, proceeding to cases where cost is altogether a secondary consideration, and supposing it possible that telegraph engineers are fairly satisfied with the quality of the protection at present supplied to submarine cables, I would ask them (not pretending to know anything at first-hand about the matter) whether a number of obscure and unexplained faults do not develop themselves in the gutta percha of cables; whether it is not possible that some of these are due to electric waves of high potential which have got into the core and punctured its dielectric at previously weak spots; whether, indeed, such faults are not found occasionally to develop in the wake of a storm!

I would also point out the fact that a lightning switch is found damaged, or its wire, perhaps, fused by a flash, is no proof that it has entirely protected the cable from hostile influence. It shows that it has done the best it can; but since that best falls short of perfection, the damage to the protector, proving that there has been occasion for its activity, proves likewise that the cable has been in a position of danger, has received some proportion of the damaging current, and in all probability has suffered some amount of deterioration. The voltage which plays about in the very feeblest form of statical discharge is so enormously greater than anything ever developed by ordinary voltaic batteries, that one cannot regard with equanimity the entrance of any portion of such electromotive forces into the delicate vitals of a cable. Remember that a millimetre spark means 3,000 volts.

To illustrate by experiment the assertion I have virtually made—that no conceivable form of single air-gap, whether it be between knobs or points, or plates or wires, or between wire and tube, or coil and cylinder, or any other possible device, can possibly afford complete and adequate protection—I take the following simple instances:—

Experiment No. 1.—Arrange a small air-gap, as, for instance, between the knobs of a common "universal discharger;" connect the ends of a tangle or loop of thin covered wire, one on each side of the gap, and pass a Leyden jar discharge across it. The insulation of the thin wire is sparked through wherever two portions happen to come close enough together. [The wire actually employed had been the secondary of an old induction coil, and had been well soaked in paraffin.]

Experiment No. 2.—Diminish the air-gap until the knobs actually touch. The sparking at the crossings of the tangle are rather less bright and numerous than before, but they still frequently occur.

Experiment No. 3.—Instead of an air-gap, however short, use a foot or two of stout No. 0 copper wire or rod of highest conductivity, and shunt this with a thin wire tangle or coil. On passing a discharge along the rod, the crossings of the tangle sparkle as before, showing that the double insulation is still broken down.

These extremely simple observations establish the position I hold, that no ordinary protector can switch the whole of a flash out of a coil; for a solid copper rod, no matter how thick, is unable to do it, although such a shunt as that would divert every appreciable vestige of signalling or other useful current. The fact is that to sudden discharges the impedance of a short copper rod may run as high as 100 ohms; and if the discharge current while it lasts is 100 amperes, which is a very moderate value, then we see at once that the E.M.F. needed to drive the current through the rod is 10,000 volts, and this is, therefore, for an instant, the difference of potential between its ends. Such a difference of potential can leap three or four millimetres of air, and is amply sufficient to burst through the insulation of silk-covered wire several times over.

The particular mode adopted in these and such-like experiments for sending a Leyden jar discharge through the rod or across the air-gap is quite immaterial; any convenient plan serves, from simple hand-discharging tongs upwards. But, once more, I may say that the handiest method of working is to use a couple of jars, to connect their internal coatings with the terminals of an electrical machine, the distance apart of whose terminals regulates the energy of the discharge employed; and to connect the outer coats of the jars to the two ends of the rod, or to the two rods of the universal discharger, or to whatever the flash is wanted to pass through. Instead of a wire tangle or loop, which only typifies the coil of an instrument, and whose only advantage is that one has no compunction in spoiling it, I next proceed to employ an actual galvanometer, and take it as representing anything requiring protection, whether it be telegraph instrument or cable or electric light installation of any kind. A galvanometer serves pretty well, because it indicates whether any disturbing current passes round it or not. Notice, however, that it only indicates properly when the discharge really goes round the coil. If it jumps across insulation, and, still more, if it jumps from terminal to terminal, the needle indicates less or nothing. There are, in fact, two things to be aimed at and considered separately in the protection of instruments:—

First: the current has to be prevented from passing round the coil, and thus disturbing the magnetism of the needle.

Second: it has to be prevented from jumping across from layer to layer, and so damaging the insulation.

Conduction protection, and insulation protection: both must be attended to. To carry out both these protections completely is not easy; but I apprehend that the protection of the insulation from permanent damage is usually more important than the elimination of temporary disturbing currents which interfere with signalling and make the needle kick while they last.

* Paper read before the Institution of Electrical Engineers, on April 24, 1890.

Digitized by Google

The galvanometer I use is a simple reflecting instrument, of a pattern devised by Prof. Stuart, at Cambridge, some time ago. A copper iron junction momentarily touched with the finger demonstrates that it is in a sensitive condition, and could easily be made to furnish its effective constant were it worth while. Connecting its terminals to the outsides of the pair of Leyden jars whose knobs are attached to the machine, separating the machine terminals about the fiftieth of an inch, and turning slowly, we see an attempted steady deflection representing the charging current, interrupted by a series of reverse kicks which occur at every minute discharge; though the sparks of any discharge such as is safe to send through the instrument are too faint to be heard.

Experiment No. 4.—Now insert between the wires leading to the galvanometer a sort of lightning-guard: a pair of plates mounted on a sliding arrangement, so that their distance can be varied (Fig. 1). Directly the plates approach within sparking distance, the galvanometer is apparently protected, and its kicks cease, even though by extending the machine terminals further the energy of the discharges be increased.

Interpolated Experiment No. 5.—Although not immediately important, a little fact may here be noted. If the plates of the guard are pushed still nearer together, or lightly pinched together, so as to leave only a microscopic interval, and almost to obliterate the existence of a spark between them, the needle of the galvanometer again begins to kick at every discharge; but this time wildly and irregularly, and sometimes in the reverse direction. Occasionally these disturbances are very strong, and the spot of light disappears; only to be recovered by tapping the instrument. At the instant when these kicks occur, the plates are momentarily short-circuited, as may be proved by replacing the galvanometer by a Léclanché

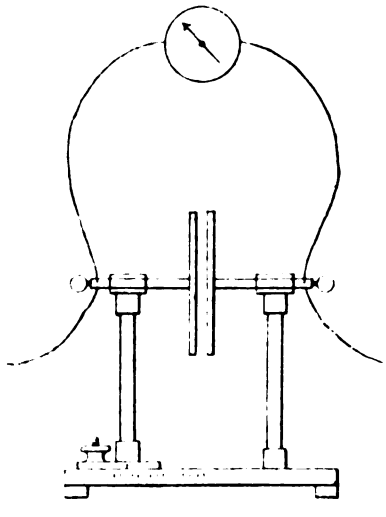

Fig. 1.

and electric bell. The bell is liable to ring at every discharge, and obviously for the same reason as the galvanometer kicks.

But whereas the bell only proves momentary conducting contact, the galvanometer proves this plus an electromotive force of occasionally uncertain direction and always uncertain magnitude. This E.M.F. would seem possibly to have something to do with the infinitesimal spark which temporarily connects the plates, and suggests an E.M.F. like the E.M.F. in an arc.*

* When I first came across this effect some weeks ago it was with tinfoil inserted between a pair of sparking terminals, and after the kick the tinfoil was often found fused on to one or other terminal. I therefore put it down to a thermal junction between tin and copper, caused and excited by the heat of the spark; and since it was a toss-up which side of the tinfoil adhered (being the side which made a just imperfect enough contact) the fluctuations of direction were easily accounted for; and by special trial this explanation was found to hold good. But then in this case after one kick the galvanometer was quiescent at subsequent discharges, until the tinfoil was disturbed sufficiently to break the fused contact again.

The experiment described in the text differs, in that there are no two metals, the metal is not fusible, the infinitesimal spark occurs between a pair of similar brass plates, or knobs, and the short-circuiting is quite temporary. I surmised, therefore, that it might possibly be a phenomenon of greater interest than a mere thermo-electric one. But after the reading of the present Paper, Prof. Hughes informed me that he had come across the very same effect, and had satisfied himself that it was only a thermo-electric one. I now think it possible that he is correct, and that the junction is caused by a momentary heat-pimple, after the fashion of a Trevelyan rocker or Gore's circular railway. And though this plausible explanation deprives the observation of any theoretical interest, I do not blot it out of the text, but leave it as a record in order to save the time of future experimenters who may easily come across the same thing

Returning now to Experiment 4, which illustrated the protection afforded to a galvanometer by a shunting air-gap, it is natural to ask how it can be reconciled with our previous observation, that protection by a single air-gap was impossible. But remember that complete protection involved two things, conduction-protection and insulation-protection; and the non-deflection of the needle merely shows that no important quantity of electricity now finds its way round the coil. But is the galvanometer therefore safe? By no means. Its insulation is in imminent danger, and if but moderately energetic flashes are employed we shall see sparks leaping across the coils or jumping from them to the metal work in a very pronounced manner.

Experiment No. 6.—As this is rather rough on the galvanometer, I prefer not to use strong flashes, but to show the existence of the tendency with smaller ones by arranging a safety valve or supplementary minute air-gap between the galvanometer terminals; said safety valve being either a couple of pins brought close together, or a chink cut across a narrow strip of tinfoil pasted on glass. The high electromotive forces which are endangering the insulation, and very likely already jumping in invisible places, can now demonstrate their existence by leaping this chink; and, no matter how the lightning-guard plates are arranged, it is impossible to check the little sparks occurring at the safety valve at every flash. Bringing the plates into absolute contact lessens the brightness of these sparks, but does not stop them; neither does replacing the plates by a solid bar of metal, as in Fig. 2.

But, directly the safety valve is employed to filter off and render manifest the residual effects left by a lightning-guard, the galvanometer needle begins to kick again whenever it acts; so that, singularly enough, whereas when no safety valve was employed the galvanometer appeared protected by the lightning switch, inasmuch as its needle is stationary, directly the safety valve is added and allowed to sparkle the needle kicks wildly with the very same flashes as before it ignored.

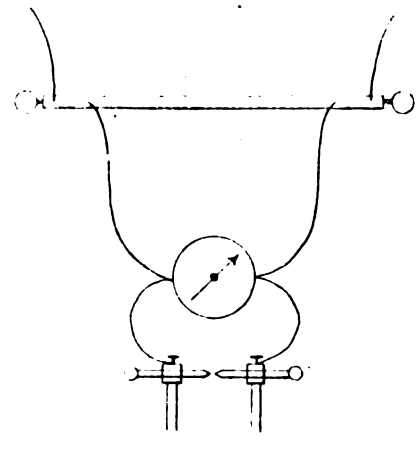

Fig. 2.

This behaviour appears to be mainly due to the same cause as produced the disturbance in the experiment interpolated above;* but it may be partly due to the weakening down of the flash by the safety valve so much that a residue of it is able to make its way round the coil, whereas it had previously been too strong, and preferred jumping across insulation in a manner ineffective for galvanometry. The possibility of the occasional truth of this latter explanation is by no means to be overlooked. It often happens that an unprotected galvanometer has its needle less strongly affected by sparks say an eighth of an inch long, than by sparks the fiftieth of an inch long; but the reason obviously is that the more violent discharges are not really passing round the coil, but are taking all manner of short cuts.

Experiment No. 7.—Instead of employing a rigged-up model of a protector, for the purpose of calling attention to principles, an actual lightning-guard may of course be used, and its behaviour studied in detail. I take, as an actual instance, a Saunders' protector, so much employed in connection with submarine cables. Its essential part is a fine wire, through which the useful currents have to pass, surrounded by an earth tube with points protruding towards the thin wire, which is stretched by a spring along its axis. The idea is that the tube will relieve the wire of dangerously high potential, while the wire itself will fuse if dangerously strong currents try to pass along it. A supplementary device is a short-circuiting contact, whereby a spring puts the cable to earth directly the wire is fused or in any other way broken. The diagram (Fig. 3)

* I do not feel quite certain of the sufficiency of Prof. Hughes' thermo-electric explanation

Digitized by Google

sufficiently represents the instrument. A Jamieson protector is a neat arrangement, involving a fine wire as well as an air-gap; there is also some wire coiled on a metal cylinder, but the metal deprives it of all appreciable self-induction.

If I now send very small discharges down the line wire towards a galvanometer protected by this Saunders' guard, they will, if small enough, escape it and pass through the galvanometer, either exciting its safety valve or disturbing its needle or both. But if stronger flashes are sent, the protector begins to act, sparks are seen between fine wire and surrounding tube, and the galvanometer disturbances diminish as already explained; but those at the safety valve never wholly cease. One is not to suppose that the bigger the flash the less the effect; that would be a very desirable but somewhat impossible conjuncture. The smallest effect is got with the weakest flash, which is just sufficient to spark to the protecting tube. Anything stronger or anything not greatly weaker than this gives larger effects.

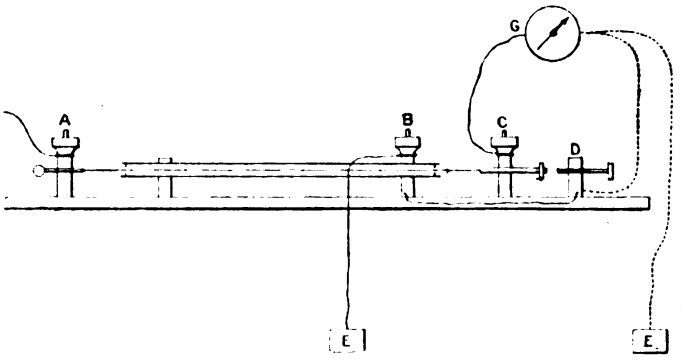

FIG. 3.

The fine wire part of this guard is a good feature and one that may be advantageously introduced into any protector, on the principle of a safety-fuse or cut-out, to eliminate steady or slowly varying currents of too great strength. But the short-circuiting of the protected terminal to earth by the terminal D as soon as the wire is destroyed, is, perhaps, not an unmixed good, for a subsequent earth-seeking disturbance has then two paths between which it may divide—if the connections are made as in Fig. 3—one along the intended earth-wire, and the other through the instrument intended to be protected.

True, this latter is a much longer route, but not so infinitely longer that it need convey none; especially if a few short cuts across insulation can be taken.

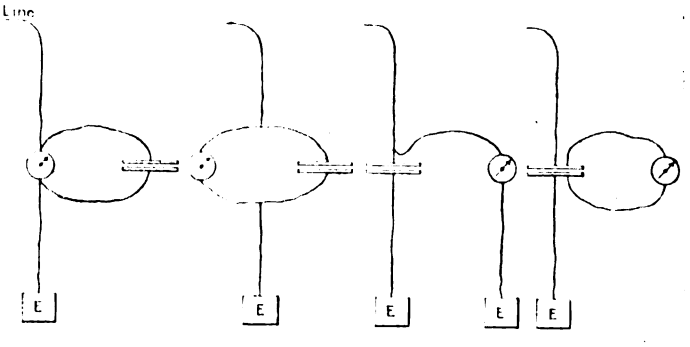

FIG. 4. FIG. 5. FIG. 6. FIG. 7.

We see at any rate how important it is to make the earth lead as short and direct as possible, and how it is better to connect the thing to be protected to the two binding screws C and D of the instrument as indicated by the dotted line, rather than to make an independent earth.* If, for instance, a cable be joined inside to C, outside to B or D, the spring short-circuiting is all good, the only objection being that however prompt the spring may be there is ample time for damage before the contact can be made.

The statement concerning the importance of a short and direct earth also applies to the desirable mode of connecting up lightning-guards in general. They should always be inserted direct into the line circuit between line and earth, never be simply led up to by side wires.

Thus, of the three modes of connecting a plate or other lightning protector to a telegraph instrument, Fig. 4 is an altogether bad mode; Fig. 5 is but little better; Fig. 6 is the same thing, or even worse; while Fig. 7 is a thoroughly good way. As I have said so often, even this is not perfection, but it is quite the best that can be done with a single air-gap of whatever kind.

Throw the leads into the protected circuit; let nothing interfere with direct connection of lightning switch to line and earth respectively, and do not use an independent earth for your instrument's earth terminal. The time taken for a disturbance to travel even a foot of copper wire is by no means to be despised, notwithstanding that it travels with the speed of light; and the impedance of every inch tells.

(To be continued.)

* The dotted line connection in Fig. 3 is the most favourable possible, and it was the one used at the meeting. It is far better than an independent earth for the galvanometer terminal.

ELECTRIC TRACTION DATA.

The following is a full report of the discussion on Mr. A. Reckenzaun's Paper:—

Mr. ALBION T. SNELL said that Mr. Reckenzaun's very interesting Paper was so teeming with notes, figures, and information, that one had hardly the time to grasp it; and therefore he felt scarcely able to do justice to it. He had not expected the author to have spoken so much about traction, pure and simple; he had, indeed, expected that Mr. Reckenzaun would have given a great deal more data about accumulator cars, about gearing, about motors, and so on. He was connected with the Electric Traction Company, in conjunction with his friend Mr. Fraser, and had been making experiments with accumulator cars for some five or six years. He had made a few notes before attending the meeting with a view of speaking on them, but as Mr. Fraser was present he would not go very closely into the details; he would merely deal with them in a rough way, and leave Mr. Fraser, who had had entire charge of the tramcar department for the last three or four years, to deal with the details. They had at Barking six cars, one of them in reserve, and they made on an average about 250 car miles per day. Their coal consumption was about one ton per day; their traction averaged between 20lb. and 30lb., which was almost identical with the figure given by Mr. Reckenzaun. The electrical horse-power per hour per car mile was, as near as could be, one. That also, he thought, agreed with the figure given in the Paper. He had had to do very largely with electrical traction under other conditions; he had had to haul by means of moving ropes in collieries, and also to work by means of locomotives on colliery rails. There they had to deal with a different state of affairs altogether. The rails in collieries were by no means so good as those which were used on tram lines; they were of a different character. The most common form of rail in collieries was the bridge rail. Another form, which was worse still, was the T rail. Then there was the ordinary one, which they knew so well. In designing a plant to work on such rails, where the traction often reached as much as 70lbs. a ton, it was necessary to make experiments to ascertain as near as possible what the traction would be for each particular case before they designed the plant. He had used the following equation for determining the manner in which the horse-power would be spent—

$$\text{H.-P.} = \frac{W\,K\,N}{33{,}000} + \frac{W\,2.240\,N}{33.000}\sin\theta.$$

They would see the importance of using it when they considered the high value of the resistance. W was the weight in tons of the total load; K was the resistance to motion, including the friction of the tub axles; N was the speed in feet per minute, and θ was the angle of the inclination which they were working on. If they were pulling a load up hill they would have to use the positive sign. If they were going down hill the chances were that the load would tend to gravitate. Then, the second term of the right-hand side of the equation might be greater than the first term. When he first entered upon this class of work he imagined that K would probably assume the proportions of about 40 to 50; but on making experiments by means of dynamometers, that is to say, putting the car on as level a piece of rail as he could get, placing the dynamometer in the rope and hauling it slowly, he found on taking measurements that the value of the coefficient of resistance averaged 70 on lines of the best type, that is with the bridge or vignole rails; but that it would rise as high as 100 even on T rails, or other rails worn flat. So that the first term of the equation might under certain conditions assume relatively large proportions. This high value of K was due primarily to dirt on the rails and the friction of the tub axles. He had known the value to be so high in some cases that the load would not gravitate on an incline of 1 in 12. Of course, in tramcars they had not to deal with such conditions as these. The ordinary sunk rail was very different indeed. At Liverpool, he believed they used the centre flange wheels with sunk rails. He had no data himself as to the resistance, but he took it that the friction would be more than that of the ordinary rails used in London or on the other tram lines. He must congratulate the O. S. A. on the very important Paper laid before it. The curves prepared so carefully by Mr. Reckenzaun were most valuable.

Mr. FRASER said that with regard to coefficient of friction on tramcars, on lines of all sorts, and with all possible conditions, according to the weather, to the extent of scooping, of cleaning, watering, &c., he found from a very considerable experience that, as Mr. Reckenzaun said, it varied between 8 and 12 per 1,000. Ten would be 24lb. to the ton, but if he gave the coefficient in percentages, it would be found good for every possible system of weights and measures, or any arrangements they might choose

Digitized by Google

to make. The difficulty concerning the state of the track, unfortunately, was not entirely in the hands of the electrical engineers; it was much more in the hands of the Tramway Companies; they did not all of them go to the trouble either to have the roads well scooped and well cleaned, nor, above all (and Mr. Reckenzaun drew particular attention to that point), to have them well watered. Liverpool, indeed, was the only place he knew of where the track was constantly watered. That was an immense advantage, as had already been pointed out, and therefore it was not necessary for him to do more than corroborate the statement. As regards the value of the coefficient of traction, which varies from 8 to 12 per 1,000, it was necessary to take very closely into account the particular vehicle with which they were dealing. For instance, in the Newry-Bessbrook coefficients, which were mentioned in the Paper varying from 27 to 30, if he remembered rightly they referred to different trains; that is to say, in one case it would, perhaps, be a locomotive vehicle pulling another car, or two cars behind it, the total weight being so much, and in another instance it would, perhaps, be the locomotive vehicle alone simply propelling itself. Now, if those coefficients of traction were taken as they were, he believed in that case from the power exerted in taking the car over the line; and in taking a train of 1, 2, or 3 cars, they would get different coefficients of traction in each instance—erroneously, because the power which would be taken to move a locomotive car would not only include that of its own actual weight, but also the work consumed by giving motion to the moving parts of the car, which, properly speaking, should be taken into account, but in the proper place. As far as the work required to move one vehicle or more over any possible line, of course the equation Mr. Snell had put upon the black board explained all; but perhaps he might be permitted to put it in the way in which he was accustomed to use it, and which seemed much simpler. His formula was

$$W = (f \pm x)\, p\, d$$

W represented work, f the coefficient of traction, x the gradient, p the weight of the loaded car, and d the distance. One great difficulty that they had to contend with in doing this kind of work was the immense opposition offered by all horsey people connected with the ordinary tramcars. Such people did their utmost to put the thing back; and wherever an electrical engineer might go and attempt to establish electrical traction, he might rest assured that he would meet with that opposition developed to its maximum point. It had been said sometimes by high authorities that electric traction could certainly be done—it had been done twenty years ago, but that was an incorrect statement. The fact is that it had not been done, and that only a few had worked it out, and those few who had worked upon it could be counted upon the fingers of one hand. It was first necessary, it seemed to him, to prove that the thing could be done at all in a way which would give every satisfaction to the tramway companies and to their passengers, quite independently of the commercial side of the question. The commercial side must necessarily be treated in the end; but until everything was done to the satisfaction of all concerned the commercial point could very well be left out of the question.

Mr. ESSON said he was very pleased with the excellent Paper which had been read. These experiments on traction were very interesting and very instructive. In the Paper by Dr. Louis Bell, referred to by Mr. Reckenzaun, he mentioned that generally speaking the reports published on electric traction were models of how to avoid giving information; but he thought, as far as Mr. Reckenzaun's Paper was concerned, that that accusation could not be made against it. The question of cost had not been gone into by Mr. Reckenzaun; and with their permission he would make a few remarks on that interesting question, for, after all, in this mercenary age, it came mostly to a question of how it would pay. The total cost of tramway working in London varied from 10¼d. to 7d. per car mile, the usual being 9d. or 10d. Of the several companies, some paid a dividend of 9½ per cent., some 9, some 2, some 1 per cent., and some paid nothing at all. In London the tramways which cost most to run paid the highest dividends; and the very cheapest tramway they had in that district, which was the Croydon Tramway, only cost 6·71d. per car mile, and in 1888 it had to make up a loss of £281. On the Continent the cost per car mile was cheaper. In Gottenburg it was 5·57d.; in the German Union it was 6·82d.; and in Bremen it was 4·44d., so that on the Continent the cost of running per car mile was considerably less than it was in this country. When they looked at a tramway company like the North Metropolitan, with its capital of something over a million sterling, and its 40 miles of rails, having a total annual expenditure of nearly a quarter of a million, it would be found that a penny saved per car mile meant something like a total gain per annum of £25,000. In the case of a tramway which was not paying, the gain of a penny per car mile meant the beginning of a very respectable dividend to the shareholders; so that electricians and electrical engineers had everything to encourage them in endeavouring to reduce the working cost of the tramways in the Metropolitan District. A large amount of these charges, of course, belonged to fixed charges, such as office and staff expenses, maintenance and renewals, of the line, buildings, &c. He had run out the cost as nearly as possible of what the actual haulage of the cars amounted to. In the first place, for each car they had nine horses; and taking the value of a horse and his harness at about £50, the nine horses cost £450, or, taking his useful life at three years, £150 per annum. That meant something like £3 per week. Now the keep of a horse costs about 15s. per week, that came to £6. 15s., and, with attendance and so on the cost of horsing per car might be taken at about £12 per week, or 35s. per day. If they took 80 car miles as about the running per day, that came to something like 5d. per car mile, so that they had got 5d. for actual haulage for the motive power, as it were, to work the cars. Electricians had to compete against this; they had to cut down the expenses by their electrical locomotives, or their motors, or whatever they were, and they had to reduce this cost of 5d. This was what they had to guide them. It was very difficult to get the cost of steam tramways, because in this country the tramways which employed steam power generally worked with horse-power as well, so that the figures got mixed and there was considerable difficulty in analysing them, and even if they had the cost of steam tramways for a particular district it would not form a very fair comparison for the working of steam traction in another district, the conditions varying so greatly for different lines. Generally, however, the steam trams were not much lower than horse trams, so that steam up to the present had not been able to make any considerable reduction in the cost of running tramways per car mile. The lowest cost in this country at the present time is the North Staffordshire Steam Tramway Company, whose cost of running per car mile was 8·71d. Now, the conditions upon which electric traction companies were allowed to work tramcars were of a very onerous character. As Mr. Fraser very properly said, all sorts of objections were thrown in their way by the horsey people, and they had to fight a very severe battle before they could run their cars upon their lines. Of course the tramway companies' way of looking at the matter was quite rational. They said, "Here is all our rolling stock; we have so many cars, and they cost £170 or thereabouts. You must not alter our cars and make them accumulator cars, because your system may break down, and then all our cars may be destroyed." That is the first thing they said; and then, "You can take out our horses, and you can pull our cars by electricity or anything you like; but you must do it in such a way that you do not interfere at all with our lines." So that the fact is, either the electrical companies have to take the cars off their lines and substitute electrical cars, taking the loss; or else they have to do, what seemed to him to be a more natural plan under the circumstances, they had to construct electrical locomotives and haul the ordinary cars. Some years ago Mr. Elieson tried this on his Stratford line, and though the scheme does not look very rosy at the moment, some valuable information was gained during the experiments made on that line. He (Mr. Esson) tested the traction, and found that on the level parts of the line, from Stratford Church to the "Princess Alice," in the Romford-road, it only amounted to 20lb. per ton, which was very low. The line, he supposed, being new and everything in first-class condition, made the coefficient somewhat lower than Mr. Reckenzaun thought the average would be. Then, as to Mr. Fraser's remark, that the traction on the line he had to deal with was 12 per thousand, which amounts to 27lb. per ton--

Mr. FRASER: Eight to 12 per thousand.

Mr. ESSON: Twelve per thousand is the highest.

Mr. FRASER: Eight per thousand would give precisely the 20lb. you have mentioned in this instance.

Mr. ESSON: Eight to 12 per thousand. The Canning Town section is, then, very similar to the Stratford section. He would like to ask Mr. Reckenzaun what sort of dynamometer he used for making his tests. As a matter of fact they had found it rather difficult to use dynamometers. He had put in an ordinary spring dynamometer between the draw bars at the end of the car, but there was a temporary inconvenience. The first time they put in the dynamometer the engine backed, and it was smashed. The second time, however, they had taken their precautions, and they got a somewhat rough result which gave, as he said, 20lb. per ton. They had not gone very far with those experiments, but he had intended later on, if he had the opportunity, to measure the power by a hydraulic dynamometer. He should like to know whether Mr. Reckenzaun had tried that. The weight of the Elieson locomotive and the car, loaded, was about eleven tons, and they used six electrical horse-power to give them a speed on the level of eight miles per hour. That was done over and over again. Well, the locomotive weight in that particular case was considerably more than was necessary; and a properly-designed locomotive, with its accumulators, car and all, need not have a greater weight than ten tons, on which they would put a motor taking an average of six electrical horse-power. As to the cost, such an engine, with its motor and gearing, and a double set of accumulators, would cost £620. Out of that there was £300 for a double set of accumulators—that was £150 each set—so that they had £320 for the motor, the car, and the gearing; and they had £300 more for the accumulators. Then they required for the generating station to charge the accumulators, 10 horse-power indicated per car, so that the amount of capital required to provide a generating station, engines, dynamos, and boilers, came to £150 per car. Altogether they had as a total £770. Taking 10 per cent. on £470, they had for renewal and maintenance and depreciation £47 per annum. Then they took 25 per cent. on £300, that was for the accumulators, and that came to £75, which made the total of £122 per annum; or, say, 7s. per day, required for depreciation and renewals. The coal used should not exceed 4 cwt. per car per day. Taking the oil and the coal together, it amounted to 5s. per day, so that they had altogether 12s. per car per day. This amount was about one-third of what horse traction came to. Providing for all contingencies whatever, the cost of traction by electricity should be very much less than horse traction, the profit on the running giving a considerably increased dividend on the larger capital required.. It was a very regrettable fact that up to the present time they had had very little chance of proving it experimentally. Tests had been made in America. In America, of course, the conditions were different from the conditions here. They had in England to work in crowded streets, and they had no overhead railways as in America. Well, in 1887 out of all the electrical railways in America, only two had the conduit rail, or a sunk rail—all the others were overhead. He need scarcely say that as regarded the cost of working, inasmuch as keeping the rails clean affect it, the overhead line had an immense advantage. Taking the very worst possible case, taking all possible contingencies into account, there seemed to be a very decided advantage in electric traction. The only pity was that they could not have some strong company to take up the thing in a

Digitized by Google

business way, and to work it on a large scale. He was afraid that very soon, if some of the larger companies did not wake up, the Americans would step in. Perhaps Mr. Sprague would have to show them how to do it!

Dr. THOMPSON said they had all of them to thank Mr. Reckenzaun for his most useful and informing Paper. When they had the opportunity of getting it in printed form no doubt they would keep it by them ever afterwards as a piece of standard literature on this subject. He had worked so little on the question of traction that he felt perfectly incompetent either to criticise or seriously to enter into the discussion of the immediate subject of the Paper; he could only express his admiration at the pains which had been taken to get at the facts in these experiments. Reference had been made to the running of cars electrically some years ago by Mr. Elieson on the North Metropolitan line to Stratford. Mr. Esson had referred to that scheme—it was something more than an experiment—that experience as having come to an untimely end. No one regretted that more than he did, for he took great interest in the Stratford line. If they examined into the circumstances of the case they would see that it was not electricity that ought to be blamed for the untimely end to which that experience came. As long as Mr. Elieson was in charge of those cars they ran extremely well, and they had very few troubles of any sort whatever; but the thing went out of his hands and passed into the hands of another firm of engineers—engineers, mind. They were supposed to be competent engineers; and lo and behold, the very first day they took the management of the thing they spoilt two engines by running them over points, the points being so misarranged that the two wheels took two separate lines and branched out one from the other (laughter). They also managed to ruin another engine by tearing the teeth out of the driving arrangements. Hornbeam teeth, properly set, ought not to have come to grief. It was a purely mechanical breakdown, due partly to the fact that the people who were running the cars did not understand, and had not taken pains to master, one very simple electrical arrangement which Mr. Elieson had introduced. Mr. Elieson had introduced a second switch to turn on a small current for the starting up of his motor before he threw it into gear. Then he had a big switch to turn on the big driving current. "Well," they said, "this is unnecessary—we will have one switch only which would be simpler to manage, and we will have the big switch." They put on the whole of the current, and got an enormous speed on the motor, and then ran it into gear, and the first time it was put into gear off went the teeth of the gear. Purely a mechanical break-down, not an electrical thing at all. A system which had worked excellently for nine months of experimental trial under Mr. Elieson broke down in three days when the working was given over to the contracting firm of engineers! When people said electricity did not do for driving tramcars, and pointed to the North Metropolitan failure in support of their argument, they had simply to remember that it was not an electrical breakdown at all; it was a purely mechanical one, which good engineering might have avoided. It was perfectly clear to everyone who had gone into statistics, and they had had a large dose of them, thanks to Mr. Esson, that the cost of *electrage* was a great deal less than the cost of *horsage* for cars; and the sooner that was brought to the minds of directors of tramcar companies the better it would be for them all. If directors could only be assured point blank that it was to their interest to turn out the horses and put in the electric motors, they would do it in the hope of earning bigger dividends, and of having the honour and glory of being the first people in this country to run electric tramcars successfully. One point he would certainly like to have heard more upon from Mr. Reckenzaun was the question of driving gear in the motors. The author had had so much experience of so many different kinds of gearing, that probably he had an opinion well settled, and consequently worth learning, as to what was the best kind of driving gear. Lastly, he would like to express his admiration of those diagrams, and of the patience which that man must have had who had to look at the ammeter during all that time. He put it to Mr. Reckenzaun whether it would not be worth while for this purpose, if for no other, to devise some kind of recording ammeter, which would take down the record minute by minute, instead of having to keep that sagacious individual on the watch. There were some recording ammeters now, but they were not very satisfactory for putting behind the tramcar. There were some little things made by Richard, of Paris; but they were not very satisfactory things, certainly not very satisfactory if they were to be put on behind a vehicle which would have to go bumping more or less over an uneven track.

Dr. SUMPNER said that recently in one of the American periodicals Mr. Hutchinson, of the Sprague Company, had published several figures showing the relation between the expenses on five lines in different cities of America driven electrically by the Sprague Company, but not driven by accumulators. The absolute cost was not given, only the relative cost. One item was the cost of carmen, which he assumed included not only the cost of the men employed on the cars, but the ordinary office expenses. Another item was the cost of maintenance of the line, and the cost of the driving power was put down as a third item. On a very steep line, grading 6 per cent., the cost of the carmen came to 71·5 per cent., the cost of the maintenance of the line to 1·8 per cent., and the cost of the electrical power to 26·7. On a line, which on the whole was a level line, the cost of carmen only came to 67 per cent., the maintenance was 18, and the cost of the electrical power 15. On another line, also level, the cost of the carmen was 65·5, maintenance 12·7, and electrical power 21·8. The mean result from all the five lines was: cost of carmen, 69·5; maintenance, 11·5; and electrical power, 19 per cent. Till he had seen those figures he had no idea that the cost of the electrical power bore such a small proportion to the entire cost of the line. In the item of electrical power was included labour, fuel, oil, and waste. The 19 per cent. was made up of 11 per cent. labour, 6·3 fuel, and oil and waste 1·7; so that the cost of the fuel only came practically to 8 per cent. of the whole, whereas Mr. Reckenzaun stated that the traction expenses on horse tramways came to about two-thirds of the working expenses of the line. No doubt, however, that item of traction expenses included some of the things that he had just put down in the cost of carmen, and he would like the author of the Paper to give fuller information on the point. The small ratio of the traction expenses to the whole would prevent existing companies from changing their system, while it would render new companies less reluctant to adopt electric traction.

Mr. RECKENZAUN, in reply, said that Mr. Snell had given them very useful information, and that the formula which he had mentioned had been published before. Mr. Fraser made one very serious remark; he said that the commercial point could be left out of the question. Now, in his opinion, that really was the first question, for unless electrical traction was very much cheaper than horse traction it was no use experimenting with it, or spending money, or time, or brains upon it. He was perfectly convinced that electrical traction was very much cheaper than horse traction, and the first thing to do was to show that practically it was. Mr. Esson went through a long series of figures with regard to traction cost on the various Metropolitan tramways. He himself had gone through those figures year after year for the last seven years, and he knew most of them, but he did not propose to go into them then—because, first, he had not time to cover so large a field; and, secondly, he read a Paper before the Society of Arts about three years ago, which covered the ground very largely. Of course, since then much more had been done. Mr. Esson was right in saying that the conditions in America were very different from what they were here. In this country one of the greatest drawbacks to electric traction, or any other traction—even horse traction—on tramways was the public authority. It took many years to introduce tramways in England after they had been a perfect success in the United States and other countries. Six years ago when he wanted to run cars experimentally on one of the lines in London, he had first to obtain the permission of the Board of Trade. Major-General Hutchinson came twice to see the car, and to judge whether it was perfectly safe to use in the public streets. Then, after two or three months' delay, he got permission from the vestries to run a car for a few days on the line, and he did run it; but there it ended. He was not a rich man, and he had no financial support. He did not get the support of the tramway company. They said, "You can run all our cars at your own expense on our lines, if you like; but the first thing you must have before you can run electric cars on our line is an Act of Parliament. An Act of Parliament will cost you from £1,000 to £2,000—we do not know exactly—and it will take a year or two to get it." That was the sort of thing people had to contend with in this country when they desired to introduce electric traction. The Americans could do just as they liked. He did not say that was an advantage, but he thought it had shown itself to be an advantage, because there were now over 1,000 miles of electric railways in the United States, carrying from six to seven hundred cars, and there were as many more at the present time in course of construction. Mr. Esson had asked what sort of a dynamometer he used. He had not used any dynamometer. The cars he experimented with were all self-contained cars, and they did not draw anything else behind them, so the dynamometer they used was an ammeter, and he assured them that it was the most delicate and the most accurate dynamometer they could use. He was not going into the cost of electric traction, nor into the question as to the adoption of accumulators. That was also a separate subject which he had dealt with on various previous occasions. The great question which Dr. Thompson gave him was on the best kind of gearing to be used. On this subject also he had read a long Paper before the American Institute of Electrical Engineers about two years ago, which turned exclusively on gearing for tramways. There he had enumerated the numerous experiments which had been made in chain gearing, spur gearing, friction gearing, rope gearing, and worm gearing. That question was not quite decided yet, and it was a very difficult question. Spur gearing was very economical, but noisy, and very objectionable on account of the noise. Chain gearing was very troublesome, because the distance between the centres of the driving wheels and the driven wheel was necessarily short, and there was no elasticity in the system, so that when there was a slight expansion, or, perhaps, he should say elongation of the chain, there was always a danger of a link of the chain riding over a tooth, and breaking the chain to pieces. With a long chain there was a certain amount of slack, which took up a small amount of expansion; and chain gearing had been very troublesome on that account. It was also noisy. He used a worm gearing, as everybody knew, of a special design, which gave very great satisfaction; it was not quite so efficient as spur gearing, for instance; but it was very durable and silent. With regard to Dr. Thompson's suggestion that there ought to have been some device for automatically recording the readings, that would have been a very useful thing. On one occasion they made two trips of seven miles each, in the course of 2¼ hours, and he took every reading himself. He assured them he was perfectly crippled; he stood in one particular position the whole time, doing nothing but writing down figures at a given speed ratio. Until he had drawn out the diagrams within the last few days, he had not himself been aware that there were such enormous variations in the tractive force. Dr. Sumpner was surprised at the relative expenses of men, maintenance of line, and cost of driving power in the United States. He need not be surprised if he knew that the car-drivers and the conductors get $2½ a day wages—those were the lowest wages, for in the Western States they got as much as $3 a day, and the wages of the men at the central stations were similarly high. The only way in which he could explain the figures given by Dr. Sumpner was, that the men's wages being so high they formed a large percentage in the total cost.

A vote of thanks was then accorded to Mr. Reckenzaun for his Paper, and the meeting terminated.

THE RAILWAY RATES INQUIRY.

FRIDAY, May 9th.

Lord BALFOUR OF BURLEIGH said that the Court had received an application from the Postmaster-General to be heard in reference to the classification of certain articles.

Mr. STUART, of the Post Office, said the articles in regard to the classification of which the defendant objected were "telegraph poles," "insulators," "copper wire," "bare copper wire," and "copper wire covered with gutta percha."

Lord BALFOUR OF BURLEIGH said the Post Office did not seem to be aware that written objections and the reasons for them ought to have been lodged in order that they might be heard as each article was reached. The articles mentioned by Mr. Stuart had already been passed, and it would be inconvenient to go back to them, especially as the Court had received no written objection or reply from the railway companies. He thought the best course would be for the Post Office to send in written objections, stating where they wished these articles to be classed, and why. Their communication would then be sent to the railway companies for their reply, and the Court would then fix a subsequent day for dealing with the matter.

Mr. COURTENAY BOYLE remarked that in his official letter the Postmaster-General assigned no reasons whatever for his objections, but simply said that certain articles ought to go into a lower class.

SATURDAY, May 10th.

Class 3 was again under consideration.

Dynamos and Electrical Machinery not Packed.

Mr. TROTTER said the objectors were satisfied with the companies' proposals.

Electric Cables.

Mr. TROTTER said he appeared to uphold the objection to the classification of this article. The phraseology of the railway companies was literally identical with that of the telegraph cables, which they said were included in the term "electric cables." There appeared to be a remarkable impression about the way in which cables were sent. They were a comparatively new article of manufacture, rapidly increasing, and of decreasing value. He had made careful inquiries of almost the whole of the electrical trade, and the very suggestion "that frequently the cable has to be coiled on to the waggons, and uncoiled for delivery," had never been heard of, and had caused considerable amusement. The makers had never heard of such an instance, and he challenged the railway companies to give him a single instance where a cable had been sent in this manner. As to the same objection being applied to telegraph cable, he had applied to a gentleman who was undeniably the highest authority—Mr. Preece, of the Post Office—and to other engineers in H.M.'s Post Office, and he found, in the course of Mr. Preece's 38 years' experience, there were only three cases that he could remember in which a submarine cable had been loosely coiled on to the trucks, in cases of extreme urgency, where they were compelled to do it; and he has had experience of 118 submarine cables for telegraph purposes. Submarine cables were sent naturally by ship; they were loaded on board cable ships, and they were very rarely sent by rail.

Lord BALFOUR OF BURLEIGH: How are they carried on the railway?

Mr. TROTTER: In these three instances I believe the Post Office would tell you they were loaded most carefully by the Post Office officials on trucks, and taken off again by them in long lengths and "shore ends," a heavy armoured cable. Those are the only three cases I can hear of.

Lord BALFOUR OF BURLEIGH: In those cases they were specially loaded?

Mr. TROTTER: Yes.

Lord BALFOUR OF BURLEIGH: How were they loaded?

Mr. TROTTER: I cannot give details. In the three cases they were coiled up as the railway company states. That is the nature of our objection. The usual way is to put them in canvas coils, but generally a large consignment of cables is put on large wooden drums, the drums being lagged or boarded over, and it is absolutely impossible that damage can occur to them. Some are 10ft. in diameter. There was a cable laid down in Victoria-street in that manner.

Lord BALFOUR OF BURLEIGH: How much loading is there in a truck?

Mr. TROTTER: Any amount up to the maximum weight. The weight of cables is increasing now in consequence of the increased use of lead, copper, and iron cables. If I might put in these advertisements your lordship would see the amount of iron and lead used in many cases, and that decreases the value per ton.

Lord BALFOUR OF BURLEIGH: What is the value?

Mr. TROTTER: £32 to £48 per ton for lead-covered cables, up to £70 or £110 per ton for the ordinary electric cables, which consist of copper and insulating material only. Those are the average values which I have obtained from several makers. The value is decreasing per ton on account of the increased use of lead and iron, and also because there are various substitutes which are now being introduced which are cheaper than india-rubber.

Lord BALFOUR OF BURLEIGH: Is there a tendency to make these articles more valuable and more intricate than they used to be?

Mr. TROTTER: I think not, for this reason, that larger cables are being used now, and the mere fact that cheaper things than india-rubber are being employed for insulation, and lead and iron coverings make the value per ton considerably lower than it was a few years ago.

Mr. COURTENAY BOYLE: Now, surely the term "electric cables" covers articles of both descriptions and bulk; it would cover the main line of an electric lighting company, which might not be thicker than a thumb; and it might cover the concentric copper cable of the London Lighting Company, as thick as a man's leg.

Mr. TROTTER: The copper cable of the London Electric Lighting Company is made in lengths, and it would be rather a conductor than a cable. It is a special article; but I can assure you the values of different sizes of cables up to a half inch section of copper——

Mr. COURTENAY BOYLE: Half-inch section—how would that be carried; would it be carried in coils?

Mr. TROTTER: Yes; coiled upon a wooden drum. It would look like a large, flat, cheese-shaped cask.

Mr. COURTENAY BOYLE: Would not the term "electric cable" cover an ordinary service wire of an electric lighting company?

Mr. TROTTER: Certainly.

Mr. COURTENAY BOYLE: And that would not be coiled over a drum?

Mr. TROTTER: Very generally it is coiled on drums. Otherwise it is sent in canvas-covered bundles. But that is only on a small scale. I saw last night in High-street, Kensington, such drums standing in the street. The conductors are covered. The small-sized cables are worth £75 per ton.

LORD BALFOUR OF BURLEIGH: What have the railway companies to say?

Mr. WILKINSON (Great Western Railway): We have not much to say in answer. The term "cable," as used by us, applies to other than electric cables. Our answer applied to cables generally, not specifically to electric cables. Our present powers are the highest powers in the proposed classification; but we ask you to consider those articles the fourth in the schedule. We think it is reasonable, having regard to value, bulk and risk.

Mr. TROTTER: The definition is "electric cables," and they prefer to include telegraph cables. I am not aware of any other cables. I passed it over when "cables" came up. The word "cable" does not appear in this schedule of class 3, so I waited till "electric cables" came on; but I am not aware that they are used for any other purpose than for the conveyance of current for electric lighting purposes, and for the transmission of power, or telegraphic purposes.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 30, 1890.

Execution by Electricity.—It had been generally supposed that after the numerous legal delays already secured on behalf of the condemned murderer, Kemmler, he would be executed by electricity, in pursuance of the law which has caused so much discussion. Everything had been made ready for the execution, which was to have occurred in the week beginning April 28th. The apparatus for execution had long been ready for use, and had been elaborately tested. The New York daily papers had haunted Auburn Prison for weeks, and had been making the most elaborate preparations to secure a full report of the affair, the law to the contrary notwithstanding. They had begun to publish pictures of the apparatus, the prisoner, and everything intimately or remotely connected with him, and numerous reporters were hanging around, when their hopes of a sensation were blighted by the arrival of a writ of *habeas corpus* reprieving Kemmler, and transferring his case to the United States Courts, where a hearing will be had on June 3rd. The grounds for the transfer were based on the provision of the constitution of the United States, that cruel and unusual punishment cannot be inflicted; and this affords an opportunity for an additional delay, and by so much to delay the time of Kemmler's death. Extraordinary pressure has been brought to bear in every direction to secure his escape, and active efforts will be made for the repeal of the law itself. Kemmler is poor and friendless; the men who are defending him are not particularly noted for philanthropy, nor are they sufficiently young in the profession to incur the immense amount of labour they have for reputation or glory; somebody is paying for all this legal wrangle, and that somebody is popularly supposed to be the Westinghouse Electric Company, although nobody yet has been able to get any definite proof in the matter. The daily papers, however, seem to be unanimous in that opinion. It would be far better for the electrical fraternity at large if the law were repealed, than to have the prisoner escape through a declaration of unconstitutionality.

Storage Battery Traction.—There is great talk just now about the probable growth of storage battery traction in this city. The Julien Company are intending to make important

Digitized by Google

extensions of their system immediately, and it looks as if the storage battery car were to become a regular part of our rapid transit system within a short time. The cars in operation so far have run quite successfully, in spite of the fact that they are operated on old horse-car tracks, the rails of which are hardly heavy enough for a storage battery car. It is reported that experiments have been carried on in this city with a view of developing the alkaline storage battery, which was brought into notice some time since in France. Whether anything will come of the experiment remains to be seen; but the line is not an unpromising one, in spite of the low electromotive force of such a battery. The similarity of the alkaline storage battery to the Edison-Lalande battery is very marked in some respects.

The Westinghouse Electric Railroad Company.—The Westinghouse Railroad Company, to which I referred in my last letter, will enter the field with a 500-volt constant potential motor, very similar to those now in use. The motor is to have a Gramme armature, so it is said; and more attention has been paid to improving it in mechanical details than to making any radical departure from the present practice in its electrical features. The new company is backed by a large amount of capital, and has already secured contracts. It is very probable that the result of its operations will be to cheapen street railway electric apparatus in this country. Practically all the work up to the present has been in the hands of the Sprague and Thomson-Houston Companies, and they have recently entered into an amicable agreement not to cut each other's throats, which means that an active opponent will have a fair chance to fight, although he will have to encounter both the powerful companies just mentioned.

Alternating and Continuous Currents in relation to the Human Body.—The physiological experiments recently reported in the English papers attracted considerable attention here. The results seem to American electricians rather sensational, as they are hardly willing to believe that an alternating current is 47, or thereabouts, times more dangerous than a continuous current of the same nominal voltage. That certainly is not in accordance with the results of experiments made here, which, although they show the alternating current to be distinctly more dangerous to life than the continuous, show no such ratio between their destructive effects as was suggested in the Paper referred to.

CORRESPONDENCE.

"ALTERNATING v. CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I must again trouble you, on behalf of Dr. Harries and myself, for a little space to reply to the correspondence on this subject in your last week's issue.

Mr. Kennelly deals with a physiological effect which we did not enter upon, for the reason that it does not affect the real conditions of the problem. Deeply interesting as the question of the extent to which polarisation forms a part of the apparent resistance of the human body to continuous currents may be, any differentiation between apparent and real resistance does not assist us in arriving at the danger-ratio between the two forms of current. The apparent resistance, composed of real resistance and the counter E.M.F. of polarisation, is what has to be taken into account, because the two together act as the one factor which has to be overcome by the E.M.F. of the generator. When considering the broad question of the quantity of current (at a given E.M.F.) which will pass through the body, we cannot "eliminate the effects of polarisation," for the simple reason that the counter E.M.F. acts to all intents and purposes as a real resistance.

The ingenious method for eliminating the polarisation effect when measuring by Wheatstone bridge, devised by Mr. Kennelly, is worth attention, and we thank him for making it known. We cannot, however, agree that the "disparity between the resistance of the human body to continuous and rapidly alternating currents, as measured by the Wheatstone bridge," may *not* be attributable to some "property peculiar to living organisms." That there is some similarity between the living body and a simple polarisable electrolyte, such as water, we freely admit; but the human body presents a condition entirely *sui generis*. Its physiological actions and reactions are so complicated that the effect of electricity thereon is not to be gauged by comparison with any inanimate electrolyte. Further, the great amount of body *individuality*, both physiological and pathological, renders the problem still more difficult. That "lately killed bodies of animals" and preserved "moist flesh" approximate to the condition of the living body in things electrical, as well as in other things, may well be the case; but even your correspondent admits it may be in a much lower degree.

We venture to think that there is too much tendency to deal with the question either from the purely electrical or the purely physiological side. The two cannot be fairly separated. On the one hand, the body is not an ordinary conductor, nor *is it like any ordinary conductor*; on the other hand, physiological data—so far as they concern the *living* being—can only be considered in relation to *all the parts of that being*. Total resistance and sensation, are, therefore, all we need take into account in our consideration of the matters dealt with in our Paper.

The letter of Mr. Sayers calls for little further comment. The first part is sufficiently answered by my letter in reply to Prof. Forbes, which appeared in your issue of April 11th; while, as regards the latter part, I may point out that we purposely did not draw any conclusion as to "what is the ratio between the muscular fixation E.M.F. and a fatal E.M.F.," because we do not think sufficient is at present known on the subject to warrant any such conclusion.—Yours, &c., H. NEWMAN LAWRENCE.

The Institute of Medical Electricity.

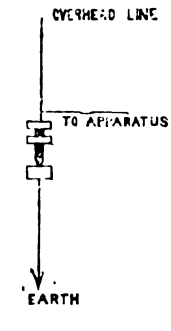
LIGHTNING PROTECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There is one feature in the lightning protector of Dr. O. Lodge, as figured in your issue of May 2nd, which might cause failure in actual practice. That is in the proposal to cause the lightning discharge after entering the apparatus to abruptly turn to right angles on its way to earth, while at the same time providing a somewhat symmetrical passage from "line" to "cable."

We have used upon our lines lightning protectors similar in principle but differently arranged for 18 years, without the instruments protected having suffered in a single instance from lightning.

As our form is based more upon the idea of providing a direct path for the lightning discharge, rather than of turning it aside by obstructions in the shape of impedance coils, I send a sketch of the arrangement.



The line is brought in with as little deviation from a straight line as possible, and faces the earth connection which continues the conductor in the same direction as nearly as possible to earth. The points are $\frac{1}{100}$th of an inch apart, and convey immense discharges without being injured.

In the case of submarine cables the sheath should be continued in the same manner up to the line, while the connection between the line and cable deviates as abruptly as possible from a direct line.

Digitized by Google

Discharges of lightning pass readily through the magnet coils of unprotected instruments, and will easily dissipate a pound of copper at a time; therefore it would not be advisable to trust too much to the obstruction of impedance coils.

The oscillations which take place in lightning discharges are not frequently visible in practice. They are, I think, only seen in the induced discharges which take place when a flash of lightning occurs in a direction parallel to an overhead conductor. These are usually of high potential and little heating power. In the other more destructive kind the discharge or discharges which precede the lightning stroke will magnetise needles in one direction, while the overhead conductors are becoming charged under the inductive influence of a thunder cloud and in the reverse direction when the lightning flash takes place.

When the primary lightning flash discharges through a tele graph circuit, which sometimes takes place, there must be no abrupt turns in the conductor, or the lightning may take unexpected courses.

In a case at Whitechapel a few years ago the lightning struck a house and divided between various conductors, one of which was the lead in of an overhead telegraph line. The copper conductor of this lead was blown out completely from the junction of the line to the instrument, except where it had passed in almost a rectangular manner over the parapet; there the lightning had made a short cut and thrown the coping into the street, killing a boy who was underneath, but leaving that part of the conductor intact.—Yours, &c., F. HIGGINS.

17 and 18, Cornhill, E.C., May 8, 1890.

ELECTRIC TRAMWAY SYSTEMS.

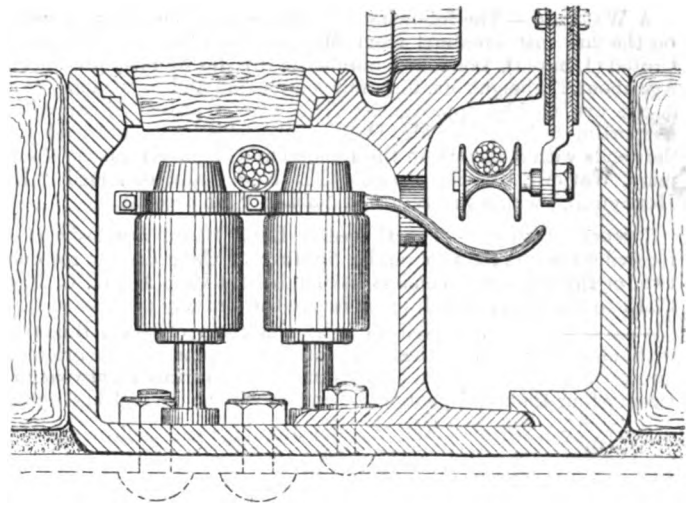
TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of last week you publish a description of an electric tramway system called the Waller-Manville, for which several features are claimed as new. I beg to point out to you that this system is by no means new, having been patented by me in 1887. In my specification (Improvements in Electrical Tramways and Railways, No. 14,029, October, 1887), a copy of which I enclose) will be found a full description of this method of insulating and collecting from a flexible cable. To Mr. Volk, of the Brighton Electric Railway, is due the credit of having first employed insulators of the telegraphic form for an electric tramway system (see specification No. 9,388, August, 1885), and also of providing removable lids, allowing access at all times to them. Mr. Volk, however, *fixed* his conductor to the insulators; and it was to get over the difficulty caused by the breaking of the insulators that I designed the system with a flexible cable *resting* on hooks supported by insulators, as shown in my specification and your description of the Waller-Manville system. This method of insulating and collecting from the conductor is the very essence of my system; and it will be seen on comparing my specification with your description that the method employed in the Waller-Manville is identical. The claims made of the conductor being removable through the slot, accessibility of the insulators, collecting arm rigidly fixed to the car, &c., are all mentioned in my specifiation; and it is difficult to see any new points in the Waller-Manville system except a slight alteration in the form of the conduit and one or two mere matters of detail of which any mechanic could sit down and work out innumerable shapes.—Yours, &c., F. C. ALLSOP.

165, Queen Victoria-street, E.C., May 12, 1890.

[In order that our readers may judge for themselves as to the identity of the two systems, we append a brief abstract from Mr. Allsop's specification, together with figure.—ED. *E.*]

"This invention relates to improvements in the apparatus for containing, insulating, conducting, and collecting the current on electrical tramways and railways, by means of which I greatly simplify the appliances, and, by such forms of conductor and methods of insulating, reduce the mechanical strain on the insulators to a minimum. In carrying out my invention I employ a channel or trough (open at the top, which top is flush with the roadway), of rolled iron or other suitable material, and of rectangular or other suitable section, and constructed preferably in lengths of about 10ft. In this channel I then place the ordinary girder type tramrail in such a position that it divides the channel into two separate parts, so that each part forms a separate channel by itself, the one preferably larger than the other. The larger one I call the 'insulator channel,' and the smaller one the 'collecting channel.' From the rail being so placed, the smaller one, or 'collecting channel,' has on the top, which is exposed to the roadway, a ¾in. slot running the entire length of it, and the larger one, or 'insulator channel,' a much wider opening, into which I afterwards fit a lid that is at all times removable, and which prevents all dirt and wet from coming into it from the roadway. In this insulator channel I place the insulators, preferably in couples with about 3ft. between each couple. To each couple of insulators is affixed, in such a manner that it is perfectly insulated from the channel, a rod of copper, brass, or other suitable alloy, the further end of which is curved preferably in the form of a hook, and passes (without touching the sides) through a hole drilled in the girder rail which forms the partition, and projects a little way into the smaller or collecting channel. On these hooks which project into the collecting channel I lay my conductor, which consists of a cable of copper or other suitable wires; this cable merely resting on the hooks and not fixed to them in any way. Fixed to the axle or axles of the car I provide a collecting arm, insulated in the usual manner, which passes through and runs in the slot in the top of the collecting channel. To the bottom part of this arm is fixed a grooved roller or rollers at such a height that it is always above and clear of the hooks that support the cable. I then place the cable over the roller so that the arm moves along with the car the cable runs over the roller, being lifted off each support as the arm passes it and falling back into its place again as the arm moves on. These rollers collect the current from the cable, and from the rollers it is transmitted up into the car by the arm, and from there by a lead to the motor in the ordinary manner. The return is effected by 'earth,' or by another cable fixed on uninsulated supports in the collecting channel and worked by a separate roller in a similar manner to the insulated cable. In cases where there are likely to be many cars at work upon the same line I provide a second "feed" conductor (*see* figure) of any



suitable form; and this conductor I place in the insulator channel and fix it in such a manner to the insulators that it is in electrical contact with the hooks that support the collecting cable. It thus feeds this cable at every hook, and by this means a larger current could be transmitted than otherwise."

DYNAMO AND MOTOR REGULATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue for May 9th I notice a reference to Messrs. Crocker and Wheeler's "Arc Current Motors." By a reference to the specification, No. 3,556, 1889, a copy of which I send you by this post, you will see that I have applied this principle to both dynamos and motors.—Yours, &c. O. FIRTH.

Bradford, May 12, 1890.

[In the patent specification referred to Mr. Firth proposes to regulate "the current developed by a dynamo-electric machine and the power of electric motors," both by moving the field-magnets away from the armature on either side of it, and by sliding the field-magnets along parallel to it.—ED. *E.*]

THE WELLINGBOROUGH AND DISTRICT TRAMROADS BILL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last week's edition you say this Bill was passed with the clauses proposed by the opponents, the South of England Telephone Company. This statement is erroneous, as the real facts are as follows:—

Digitized by Google

At the conclusion of the evidence and speeches of counsel, the Chairman stated that the Committee would insert the clause as proposed *by the promoters, the Tramway Company*, with this addition: That, if required by the Telephone Company, words should be added to carry out the offer made by Mr. Moulton of bearing the expense of protecting *existing telephone lines.*

The promoters' clause runs thus: "As regards electric circuits erected or laid down by the Telephone Company, after the construction of the works of the Company, this sub-section shall only apply if reasonable and proper precautions have been taken in the erection or laying down of such last-mentioned circuits to *insulate and protect them from external electrical influences.*"—Yours, &c.,

STEPHEN SELLON,
Engineer to the Promoter.

May 14, 1890.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

A WARNING.—The following description is given of a man who, on the 2nd inst. obtained from Messrs. Woodhouse and Rawson United (Limited), London, a number of articles by false pretences. Age about 27, height 5ft. 9in., fair complexion and moustache, cast in one eye, shabby appearance. This person presented an order purporting to be from a Mr. Honeywell, of Surbiton, and paid for the goods with a cheque on the London and County Banking Company, Watford Branch, signed "F. Hood," and endorsed "H. Honeywell," which was returned marked "No account."

TENDERS INVITED.—The Clevedon Local Board are desirous of receiving tenders for the public lighting of their district for one, two, or three years. Tenders have to be sent in to Mr. H. C. Fry, Clerk to the Local Board, on or before the 3rd day of June next.

——— It is intended to light the town of Sofia, Bulgaria, with electricity, using the water of the Boyena as the origin of force. The cost of initial establishment is estimated at twenty to twenty-four thousand pounds. Tenders will be invited in August.

SALES BY AUCTION.—Mr. Wooller Jennings will sell by auction, on Tuesday, June 3rd, at the Schmidt Douglas Electric Works, Albion-court, Bradford, and on Wednesday, June 4th, at the Repository, Canal-road, Bradford, at eleven o'clock each day, a large quantity of electric plant, machinery, and utensils. Mr. Edgar Musgrave, chartered accountant, of 1, Bank-street, Bradford, is the official liquidator; and Mr. Thomas England, Town Hall Chambers, Halifax, is solicitor to the liquidator. Further particulars are given on page xv. of advertisements, and all particulars can be obtained of the auctioneer, 43, Old Market, Bradford.

——— HORNE, SON, AND EVERSFIELD will sell by auction, at the Royal Arsenal, Woolwich, on Thursday next, at eleven o'clock, surplus and unserviceable Government stores, including theodolites, old brass, old copper, old steel, aluminium turnings, old gun metal, old zinc, old tools, old jute, and wheels. Further particulars can be had of the auctioneers, 17, Great George-street, S.W.

——— MR. F. J. BISLEY sells on Wednesday next, at Albion Works, Haymerle-road, Old Kent-road, S.E., a quantity of plant and machinery, tools, &c. Particulars of the auctioneer, 63, King William-street, E.C.

MESSRS. STAFFORD AND EAVES.—Referring to our note respecting the dissolution of partnership of Messrs. Stafford and Eaves, we are requested to state that the dissolution does not in any way interfere with the progress of the business, which is being largely extended, and is still carried on under the same style and management as before, at the Volt Works, Coventry.

DISSOLUTION OF PARTNERSHIP.—The partnership between H. Moss and T. M. Broughton, trading under the title of Moss, Broughton, and Co., at Lawson-street, Great Dover-street, London, S.E., as mechanical and electrical engineers, has been dissolved.

THE MILITARY EXHIBITION, CHELSEA.—In our note of last week we should have mentioned that the electric lighting of this Exhibition is on the Thomson-Houston system, and is installed by Messrs. Laing, Wharton, and Down.

MESSRS. RANSOMES, SIMS, AND JEFFRIES.—This firm have been awarded the first prize for Portable Steam Engines exhibited at this year's show of the Adelaide Royal Agricultural Society. The report mentions, in addition, that the engine to which the award was made was much admired for its construction and smoothness of working.

MESSRS. ERNEST SCOTT AND CO.—This firm have secured the contract for lighting the new offices and printing works of the *Bolton Evening News*. The installation will consist of 2,150 light "Tyne" compound-wound dynamos fitted with heavy fly-wheels, to be driven from two 20 horse-power "Otto" gas-engines, which also drive the printing machines, &c. The installation will ultimately consist of 400 16 candle-power incandescent lamps, and main and branch cables are provided for this number. Of this number only 280 lamps will be installed at the present time. Messrs. Bradshaw and Lass, of Bolton, are the architects, and they are supervising the installation.

NOTTING HILL COMPANY.—This Company have issued contracts to lay their mains forthwith in the following London streets:—High-street, Notting Hill; Pembridge-gardens, Linden-gardens, Clanricarde-gardens, Chepstow-place, Pembridge-square, Pembridge-place, Dawson-place, Pembridge-villas, Pembridge-crescent, Chepstow-villas, Kensington Park-gardens, Kensington Park-road, Ladbroke-square, Ladbroke-terrace, Victoria-gardens, Ladbroke-road, Notting Hill-square, Holland Park. Residents in or near these streets desiring to be supplied with light before the winter of 1890 should apply at once at the engineer's office, 105, High-street, Notting Hill, London, W.; or at the City offices, 9, Austinfriars, E.C.

MESSRS. COOPER AND CO.—We have recently devoted some space to the subject of artistic electric light fittings, and have this week had the pleasure of witnessing what can be done in illustrating the artistic application of the electric light. On Wednesday last a private view of an exhibition of this character was given on the premises of Messrs. Cooper and Co., of Great Pulteney-street, Regent-street, W., in which between 60 and 70 incandescent lamps of various candle-powers were distributed over a number of rooms very effectively furnished. Such installations should be much more frequently shown, as these displays cannot but produce an extended demand for the electric light. The numerous visitors expressed their pleasure at the display, and great credit is due to Messrs. Cooper for the effective manner in which the whole exhibition was carried out. The current was supplied from the Grosvenor Gallery.

THE QUEEN'S VISIT TO WADDESDON.—To emphasise our remarks in the above Note, it may be mentioned that the correspondents of the daily press present at the ceremonial at Waddesdon on Wednesday last are unanimous in recording the great attraction which the artistic setting of the electric lamps proved to the invited guests. This was more particularly the case with reference to what is termed "the new process" of fitting the chandeliers, pedestal lights, &c. with what appear to be wax candles, with the electric light springing therefrom. It may be mentioned that the recent fire at Waddesdon Manor was discovered by means of the electric current before much damage was done, thus preventing what would undoubtedly have proved a sad disaster.

COMPANIES' MEETINGS.

The Western and Brazilian Telegraph Company (Limited).

The nineteenth ordinary general meeting of this Company was held on the 9th inst. at Winchester House, Old Broad-street, under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice calling the meeting and the minutes of the eighteenth ordinary general meeting.

The Report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—We are not meeting to-day, fortunately, under quite such adverse circumstances as we did on the last occasion

Digitized by Google

when we came together. At that time, you will remember, we were expecting, owing to interruptions, reductions of rates, and other causes, an exceedingly bad half year's traffic, and we were threatened with a competition both north and south of our system. Opposition cables appeared to be not merely on the cards, but almost, as far as one could see, on the point of being laid. I am glad to say that the apparent darkness of those circumstances has been a great deal mitigated. To begin with, the receipts for the half-year very largely increased towards the end of the period. You will remember that when we met we were under an Empire; and we woke, either next morning or the morning after, I forget which, under a Republic. Well, now, in times of political disturbance there is always a very great increase in the interchange of telegraphic communications; and the general effect was, that during the last two months of the year the receipts were very high indeed, whereas in the four previous months they were very low. The outcome of the whole half-year of course compares unfavourably with that of the corresponding half of 1888, in which, if you remember, we took the extraordinary total of £110,000. That was the highest amount of receipts we ever realised. These large returns arose partly from the high tariff and the high rate of exchange, and partly from the enormous commercial activity and speculation that prevailed during that half-year, which recorded the highest tide-mark in respect of telegraphic revenue. The Company, nevertheless, has managed to scrape together for the last six months £86,403—no doubt, a pretty large decrease compared with £110,000; but nothing like so large a diminution as we were anticipating when we last met. I will now deal with the expenses. You will find that taking the expenditure under abstract "A." the expenses at stations, the total works out practically at the same figure as it did in the corresponding period of the previous year, the difference on the gross amounting to only £11. 6s. 7d. I take it that you will not want any explanation of this from me. In the same way, taking abstract "C," that is, the expenses in London, the totals are again so closely identical that they do not call for any explanation. The difference there is one of £61. 13s. 2d., as the effect of more work having had to be done. There was not a very great deal, but still more had to be done; and under the circumstances, therefore, these figures give us a satisfactory outcome from the point of view of commercial expenses for the half-year. The only real increase—and it is one which finds no favour with the Directors, although we find it extremely difficult to control—is under the head of "Ships." You will remember that we had to bring our own ship the "Norseman" home in order to be repaired, and that we replaced her by another called the "Buccaneer," which we took upon charter. Well, the expenses of the half-year would not have been so great but for the fact that the "Norseman" was detained by the strikes at Leith. She would have got away a great deal sooner but for those strikes, and consequently the chartered vessel would have been relieved sooner too. The result is that there is a net increase under the head of "Ships" of £6,281 9s. 7d. Of course, had we not had that vessel, the loss that we should have sustained on revenue account would have been very large indeed, because of the interruptions. As the Report tells you, there is an item for more cable used, £928, and there is an extra amount written off the ships for depreciation of nearly £900; so that it is quite correct for me to say that the increase in our expenses is owing practically to the ships and the maintenance of the cables. With respect to the repairs done to the "Norseman," they were very extensive, and of course she was sent back almost, if not quite, as good a ship as ever she was. We thought, therefore, that as we had improved her value, we should charge the amount to her account. Of course, the wages, coals, and other things had to be charged against revenue, but the actual outlay on the ship was charged to the ship. This appeared to us to be reasonable; and I hope that you, gentlemen, will think that it is right. After all these figures are boiled down we come to this, that including the amount brought forward, £4,072 9s. 8d., the dividend received from the Platino Company £7,379, the balance to the credit of revenue is £57,462. 18s. 6d. From this has to be deducted £13,500 for debenture interest, £7,500 for renewal fund, and £5,600 for debenture redemption fund. This leaves an available balance of £30,862. 18s. 6d., which allows of a dividend at the rate of 4 per cent. per annum, free of income-tax, for the half-year, and leaves £3,248. 16s. 6d. to be carried forward. I must confess that when I had the pleasure of meeting you last, I did not think that the outcome for the half-year ended December 31st would be as satisfactory as it has been. I was saying just now, that the Company went to sleep under an Empire, and woke up under a Republic. You will remember that at the meeting we held, we were discussing the steps that we ought to take with the Brazilian Government. Of course our movements were rather precipitated by what took place in Brazil. We thought that after a crisis of that kind friendly intervention might be brought to bear upon the newly-installed Government, which would prove, perhaps, to be very useful to us: and we therefore sent our papers to the English Government, with the request that they would aid us in Brazil if, of course, they were satisfied with the nature of the case we presented to them. I have not had much to do with the British Government, but I have always found that it is an exceedingly difficult one to convince. If you can convince the British Government, you may be pretty sure that your case is not very bad. Information was called for, documents were required, returns had to be made, and every information that was needed was put before our Government and fully considered by them. And I am glad to say that the result of their investigation of our case was that they arrived at the conclusion that we had a very good case, and that a remedy certainly ought to be found for our grievances. In the end the British Minister at Rio was instructed to give his friendly support with the Brazilian Government to the petition that we had sent in, and to the claims that we had made under our concession and otherwise. Of course, in a matter of this sort one Government acting with another Government can only give friendly assistance. The Brazilian Government is paramount in its own country. It can be forced to do nothing, and the only method to pursue is to act by way of persuasion, by getting up your case as clearly as you can. The whole thing is now under consideration. We have given every kind of information that we could; we have put forward every fact fairly and squarely, because we believe that our case is a good one; and the more the facts, information, and documents are put forward, as you remember we laid them before you at the last meeting, the better is our chance of success. Of course, with a new Government like that of the United States of Brazil, it is quite impossible to tell what is going to occur. We cannot say what resolution the Government may come to upon these facts and representations. We can only hope that it may be favourable; and we must continue to stand ready to do our best at all times, and, under the most favourable conditions, to continue to force the matter on their attention. Gentlemen, at the last meeting, as I said just now, we were threatened, as you will remember, with two competitive lines. One was the line from the Argentine territory to Europe; and although one does not, perhaps, feel very great surprise at the extraordinary statements promoters put forward for reaching the pockets of the public, we were surprised in that case, because the Argentine Federation had a duplicate cable communication already. They had a cable by the east coast and a cable by the west coast. These were competitive cables; and therefore there was every apparent certainty that at no time would they be interrupted, and they would have certainly every possible facility and good means of communication. Still, it was proposed to spend upwards of two millions, with a guarantee of 5 per cent. interest, at a time when the premium on gold in Buenos Ayres was something like 205 per cent. Of course, the effects of the political storm in Brazil did not stop at the coast of Brazil. The surges seemed to influence the state of things in the whole Argentine Federation; and the premium on gold, instead of going down, continued to go up. I think I remember seeing it in the last six weeks at something nearer 300 than 200. Two millions and upwards were proposed to be raised, with a guarantee of 5 per cent., which would have to be paid in gold. This, in a country where gold was at a premium of something like 275 or 280 per cent., appears to have been regarded as a thing which could not be carried out without extreme difficulty. But, as far as we can see, owing to the embarrassment of the Argentine Government, there is, at all events, no present prospect of this scheme going before the public again. That was not the only matter before investors. There was another concern between Brazil and the United States of America, which was of a somewhat similar nature in its incidence. But according to the terms of our concession that cable could only compete for a very limited portion of the traffic if it were made; and our contention is, that it could not pay with that small traffic, and there is no guarantee in this case. Consequently the scheme appears to have fallen back a bit, and I am pleased to say does not look so formidable now, and we may hope that these two schemes will eventually fall through. But people seem to be always quite prepared to come forward and subscribe money to be lost in cable operations, as though they rather relished being phlebotomised. I do not know that there is anything more for me to say except that there is to be a Telegraph Conference this year, at which all the companies will be represented. I do not know that there is anything to be feared with regard to the rates. My impression is that there will not be much done there to affect the interest of extra European telegraph lines. I might just make an observation as to the current state of things. Of course, it does not properly belong to the half-year under review; but no doubt you would like to know—you are entitled to know—that our receipts this half-year are on the whole satisfactory. You know that at the last two meetings it was our unpleasant duty to deplore the interruptions to the cables, and we told you that these things would be in one year particularly bad, and in another particularly good. Well, I am pleased to say that, as far as the year has gone, it promises to be a good one. Our receipts are averaging better than they did at the corresponding period of 1888 by some £6,800. That also is with a lower rate of exchange; and, as compared with 1889, there is also, I am glad to say, an increase of £425; so that altogether up to the present time your working promises to be satisfactory. I do not like to say anything more than that, because sometimes when we do indulge in sanguine expectations we are brought to book in round terms afterwards for it. I remember a Director of one of the Companies once saying that not one of his cables was interrupted, and when he got back to the office he was told that three of them in the meanwhile had broken down. With these remarks I beg to move:—

"That the Report and accounts for the half-year ended December 31, 1889, now submitted, be and the same are hereby approved and adopted; and that a dividend of 6s. per share, free of income-tax, making £4 per cent. for the year, be declared and paid on the 15th inst."

Mr. H. WEAVER seconded the motion.

Mr. CLARK said that the chief item of interest in the accounts was the enormous loss caused by the repair of the Company's ship. He believed that the present repairs were chiefly owing to the renewing of the boilers. If that was so, it seemed to him to be an immense amount. The total sum they had paid for their ships' repairs had been £17,000 odd, which he thought was very large.

Mr. PETO said it was always very pleasing to hear the lucid statements from the Chair, from which it might be clearly gathered that they had a very fine property, and that they had every reason to be satisfied with the way in which it had been managed. As far as he was concerned, he confessed that he would be very much pleased to have much less interest if the debentures could be converted into Debenture Stock. He was told, however, by the solicitor to the Company that there was a legal difficulty in the way. But if it could be effected he would be very glad indeed to welcome the change, as he thought it would be a very fine thing for the Company.

Digitized by Google

The CHAIRMAN, in reply, said: We have depreciated the ships regularly every year. We have usually depreciated them at the rate of six per cent. In the present case, having charged these considerable renewals to the value of the "Norseman," we thought that we might extend the figure a little, and consequently we have depreciated her ten per cent. It is about five years ago since she was repaired, and I may say, in reference to the question which the hon. proprietor put—and it is a very natural one—"has all this money been spent upon the boilers?" it has not. It was not merely the ship's boilers that wanted repairing, but her decks and masts, and in fact she had a thorough overhaul, and has been made to look like a new vessel. She has undergone a most careful survey, and has been put right in every respect. I do not want to trouble you with too many details on occasions like these, but you are aware that we were duplicating a part of the cable, a work at which she was present. There were some 284 miles of cable put into the sea. Of course we cannot give you all the details that we should like; but we are always happy to answer if we can the questions of hon. proprietors. As you are aware, we have had the subject of the debentures constantly before us. We have endeavoured to get the best advice we could about it, and we have been told that we must not move in the matter just now over and beyond the strictly legal question.

Mr. CLARKE asked how long the "Norseman" might be expected to last without further large repairs?

The CHAIRMAN: I think she ought to be good for another seven or eight years.

The resolution was carried unanimously.

The CHAIRMAN next moved:—

"*That Mr. C. W. Earle, who now retires, be and is hereby re-elected a Director of the Company.*"

Lord R. H. BROWNE seconded the motion, which was carrried unanimously.

The CHAIRMAN moved and Major WOOD seconded:—

"*That Mr. H. Weaver, who now retires, be and is hereby re-elected a Director of the Company.*"

The motion was carried unanimously.

Mr. PETO proposed the next resolution as follows:—

"*That Mr. John Weise and Mr. J. G. Griffiths be and are hereby re-elected Auditors of the Company, and that their joint remuneration be 100 guineas.*"

Mr. MACHELL seconded the motion, which was carried *nem. con.*

The CHAIRMAN: I am asked to mention something here that affects us very little now, although it may affect us in certain directions in the future, and that is that we have been discussing the question of doing something in the way of reducing our press rates. We may be shortly in a position, I think, to announce a reduction of them. That concludes the business, and I thank you for your kind attention.

Mr. PETO proposed a vote of thanks to the Chairman, Directors, and the staff for their efficient conduct of the Company's business for the past year; remarking, as he had said before, that he thought they had a very fine property, and they ought to be thoroughly satisfied with the management of it.

Mr. CLARKE seconded the resolution, which was carried unanimously; and,

The CHAIRMAN having briefly returned thanks, the proceedings terminated.

The West Coast of America Telegraph Company (Limited).

The thirteenth ordinary general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, under the presidency of Mr. Alfred Marshall.

The SECRETARY (Mr. Frederick Robinson) read the notice convening the meeting, and the Report of the Directors was taken as read.

The CHAIRMAN: We have, as usual, placed the figures of the previous year against those of the year just passed, so that you have been able to compare them at your leisure. I will, however, allude to some of the principal items. If you refer to the revenue account you will see that the gross earnings of the Company during 1889 have been £83,568. This very handsome amount has been produced by the very good traffic we have had during the past year. We attribute this to the good business which has been done on the West Coast; then to the formation of a large number of joint-stock companies, and the large speculation in nitrate, which has given us a great deal of work; and to the circumstance that the competing line on the East Coast, which competes for the traffic from Valparaiso, has for some time been interrupted, so that we have had a certain amount of traffic which would otherwise have gone over their line. I can only congratulate you on these handsome returns for the year 1889. A little further down in the same account you see interest account. At first sight it seems an anomaly that though we have had a larger amount invested in the reserve fund the interest account should show a smaller amount. The reason is that this item not only shows the dividends we have earned, but from it are deducted any discount that we may have to pay in discounting the remittances that come home from the other side. In 1889 we have had to discount a much larger amount of bills, and consequently that expense has been greater. At the same time the amount for 1888 included a profit we made in that year on the sale of stock and reinvestment—a profit which was not earned in the past year—and some dividends which were received, exceptionally, before the end of that year, and which for the year 1889 were only received in January last, and which will appear in next year's accounts. I have referred to this because I have had questions asked me on this subject, and I anticipated that some of you would require the explanation which I have given, and which will therefore save you the trouble of asking for it. On the left-hand side of the account, the only amount requiring any reference is the West Coast expenses account. These expenses have been about £3,000 higher than they were in the previous year, the reasons being that we have done more work, and we have had more clerks. The clerks, too, in time, get an increase of salaries; and more wages have been paid. We have had more rents and taxes to pay on account of the increased number of offices; and the passage-money has been heavier, because some time-expired clerks have returned from the coast, and been re-engaged, their fares having been paid. On the whole, however, the increase in the expenses is small compared with the handsome increase in the earnings. I now come to the point mentioned in a paragraph in our Report, in which we have given you the reason for adding the very large sum of £25,000 to our reserve fund, and I will at the same time take the opportunity of answering questions which have been put to us, and anticipating questions which some of you gentlemen may also wish to ask us. I refer to the threat of competition mentioned in our Report; and in order to explain this matter as nearly as I can, I will give you a small history of the way in which our Company is worked. The concession under which the cables are worked is not a monopoly; it is merely a permission of the Chilian Government, which has exercised its right of giving permission to others to lay a cable parallel to ours. As far back as the year 1887, in February, permission to lay a cable was given to Don Enrique Gandarillas, a gentleman with whom we are not acquainted. No doubt this was in the interest of the Central and South American Telegraph Company, our neighbours, who were then and are still working with us under a joint agreement. This concession came to an end in February, 1889, but the Chilian Government renewed the permission to lay the cable for a year up to 1890; and in February last they again renewed their permission, and granted an extension of the concession up to February, 1891. Meanwhile, during the present year a steamer has been sent out by the Central Company to act as a repairing steamer, and consequently the agreement which we had with them, and the retaining fee which they paid us, will not be paid to us after the arrival of that steamer on the coast. Then last month there appeared in the New York *Chronicle* a notice that the Central Company had asked its shareholders for an increase of capital to the extent of $1,000,000 United States currency for the purpose of laying cables parallel to ours. About the same time notice was sent to us from the Central Company that the joint working agreement, which is dated July, 1882, and which was terminable at six months' notice, would come to an end on October 1st next. This appeared only a few days before our Report was issued to you. Now, we believe it is not possible that by October 1st next a cable can be laid—the time is too short; but we believe it to be quite possible that a cable can be manufactured, sent out, and laid before the expiration of the concession given to Mr. Gandarillas, and terminating at the end of February. We thought it very important that the shareholders should be informed of this threat at the earliest opportunity, and therefore we embodied it in our Report, which was about to be issued with the accounts for the past year. We hope before the Directors of the Central and South American Company definitely take so serious a step, that they will suggest some new working arrangement with us. They know perfectly well that we are prepared to treat with them. If there are any questions that any gentleman would like to ask me I shall be happy to answer them to the best of my ability before putting to you the formal resolution adopting the Report and accounts.

Mr. LAMONT inquired if the Central Company was an American Company.

The CHAIRMAN: Yes, there are two companies working between Galveston and Callao. In further reply to Mr. Lamont, the CHAIRMAN said: All the European messages that we get go over the Central Company's lines also. There are two lines to Valparaiso—the Galveston route (call that our route) and the Eastern route *viâ* Lisbon, the latter traffic going over the Brazilian Submarine and the Western and Brazilian lines; but we have got our cables into such good working order that very few of the merchants in Valparaiso avail themselves of our competitors. I think we must get 80 or 90 per cent. of the traffic.

Mr. LAMONT: Are the Directors taking steps to see if any agreement can be come to, because if we enter on competition it will be suicidal?

The CHAIRMAN: The President of the Central Company has been informed that we are open to be treated with, and we are in hopes that they will do so before they take any definite steps. There may be a personal meeting of some kind between us.

A SHAREHOLDER: Have the Central Company yet obtained the increase of capital you mentioned?

The CHAIRMAN: We have not heard that they have got it, but there are powerful persons connected with the Central Company, and we have no doubt that if they are in earnest they can procure the funds they may require.

Mr. J. TAYLOR asked which way the River Plate messages of the Company would go if they broke with the Central Company?

The CHAIRMAN: The Central Company would not let the traffic go over the Western and Brazilian lines if they could help it. As long as they have not a cable of their own, we should continue to give our messages to them.

Mr. J. TAYLOR: But if they had the cable?

The CHAIRMAN: We should not get the European messages *viâ* Galveston. If we could get messages in Peru we should send them over our line and *viâ* Lisbon. Probably customers in Peru would prefer the short route *viâ* Galveston.

Mr. TAYLOR: There is hardly any question of short routes in connection with telegraph cables.

Digitized by Google

A SHAREHOLDER inquired how the Company's position would be affected, roughly, supposing the new route were made, and that there was, as he imagined there would be, distinct hostility on the part of the Central Company towards the West Coast Company. Would the latter be shut off from their present business or a great part of it?

The CHAIRMAN: If these cables were laid we should have to try and get some European traffic by the Lisbon route. We should, for instance, have to try and get Lima telegrams over our own line *viâ* Buenos Ayres, Rio, and Lisbon. They would also, of course, compete for the local traffic, and that would entail a reduction of rates.

Mr. J. TAYLOR: When the Central American Company get their cables, I should think the Brazilian Company would be very glad to make the same arrangement with you as you had with the Central Company.

The CHAIRMAN: I have no doubt they would, but it is too early to go into that matter.

Mr. TAYLOR: But not too early to look around you.

The CHAIRMAN: We are quite alive to doing what we can to protect the interests of the shareholders.

General HAMLEY presumed that the Directors regarded as authoritative the paragraph in the American paper on which all the alarm had been founded.

The CHAIRMAN: All things combine to make it certain that it is founded on truth. They have given us the notice I referred to; they have been asked if the concession is theirs, and they did not deny it; and they have got their own steamer.

General HAMLEY: Would it be improper to ask whether, in whatever communication has occurred since the alarm was first raised, the tone of the other Company has been conciliatory or hostile?

The CHAIRMAN: It has been declining to answer.

Mr. TAYLOR said he had been under the impression that the Company possessed a monopoly.

The CHAIRMAN said that the concession they had was not coupled with a monopoly. He added: The agreement with the Central Company must have worked with satisfaction up to now to that Company. The New York paper says the agreement was not satisfactory, but we regard that as an excuse. It has evidently been satisfactory for the last seven years. If not, they could have given us years ago six months' notice to terminate it.

Mr. TAYLOR thought that the shareholders had rather been living in a fool's paradise for the last two years. The fact that the traffic had been so satisfactory was an additional reason why the Central Company should step into the shoes of the West Coast Company.

Mr. LAMONT considered the Directors' fees, £1,475, were too large to be divided among three gentlemen. He apprehended that the work attaching to the directorate in the last two or three years must have been very small. He did not think that any amount of work could be shown to represent £500 a year. He presumed that the Directors did not meet more than once a week, and in present circumstances he thought that amount was excessive.

The CHAIRMAN: Though the Directors do not meet oftener than you state, still, speaking for myself, I am sometimes four or five times a week attending to the business of the Company; and, if necessary, I should do so every day. My colleagues, too, are always available. If we do not meet at the Board we come to the office and discuss matters; and we are always at hand for the negotiation of any important business.

General HAMLEY supposed that if the Directors received any message that the Central Company were disposed to negotiate with them the shareholders would be informed of the fact.

The CHAIRMAN replied that steps would be taken to give them the earliest information.

A SHAREHOLDER asked whether it would be well to strengthen the Board at such a juncture by the addition of a gentleman conversant with the whole matter, who could give his attention to it, and, perhaps, go to the other side, and see what was best to be done.

The CHAIRMAN: If it came to any negotiations, I am ready to start at any moment on behalf of the Company; and, as regards the strengthening the Board, I have been in negotiation with a gentleman who is a very competent man, but whose other duties have not as yet enabled him to join us. He then proposed the adoption of the Report and accounts.

Mr. HENRY ROBERTS seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed the payment on the 21st inst. of the bonus recommended of 2s. a share, tax free, making the return 6 per cent. for the year. He said: We have added a large amount (£25,000) to the reserve fund, and I hope this will strengthen us very much in any negotiations which may take place, and which I hope will take place; and the dividend of 6 per cent. per annum is on the whole not bad for an investment. I think this proposal will be satisfactory to you generally.

Mr. FREDERICK WALTERS seconded the resolution, which was carried unanimously.

The CHAIRMAN then proposed the re-election of the retiring Directors, Messrs. Roberts and Walters.

Mr. C. E. MASON (a shareholder) seconded the motion, observing that Mr. Roberts had been a member of the Board for many years, and joined the Company when it was in a very different position; and Mr. Walters had also been a Director for some years. The difficulty that had now arisen would give the Directors some anxious thought, and he believed the shareholders might rely on everything that was possible being done to protect the interests of the shareholders.

The resolution was unanimously adopted.

On the motion of Mr. TAYLOR, seconded by Mr. LAMONT, Mr. John Weise was re-elected the auditor.

Mr. TAYLOR afterwards referred to the large amount paid for the insurance of the repairing steamer. He believed that on this account an amount had been paid which, if it had been allowed to accumulate, would represent some £20,000. He thought the Company was strong enough now to establish an insurance fund of its own. No vessel had less risk than a repairing steamer.

The CHAIRMAN said that the suggestion should be considered by the Directors.

A SHAREHOLDER proposed a vote of thanks to the Chairman and Directors, observing that they must have had an anxious time, and that the shareholders ought to feel grateful to them.

Mr. TAYLOR seconded the motion, which was carried unanimously.

The CHAIRMAN: I thank you for your kind expressions. I can assure you that it has been and is a very anxious time for us, and we are doing everything in our power to save your property. I hope we shall be able to give you better news at an early opportunity.

The proceedings then terminated.

Maxim-Weston Electric Company (Limited).

The ordinary general meeting of this Company was held at the Cannon-street Hotel on Friday, May 9th, to receive the Directors' Report and Accounts, to elect Directors and auditors, and to transact the ordinary business of the Company. Mr. J. Blades Gooding presided.

Mr. R. M. BARLEY (Secretary) read the notice calling the meeting, and the Report was taken as read.

The CHAIRMAN: Gentlemen,—I think that the best thing that we can do is to adopt the Report as it stands. Necessarily I think it will give rise to some discussion (hear, hear); and therefore I beg to move that the Directors' Report as submitted and the accounts be adopted.

Mr. SWABY: I shall have much pleasure in seconding it.

Mr. THORNE thought they were entitled to some explanation from the Chairman before the resolution was put to the vote (hear, hear). If they carried the motion their mouths would be sealed, and they could do nothing afterwards. He would have to move an amendment that the Report be not adopted.

Mr. WOODHEAD: What is the sum of "£458 Directors' fees" for? Is it for losing the shareholders' money? I second the amendment.

Mr. CANE said that it seemed things were to be rushed through in a very extraordinary manner; and in order that such should not occur he would move another amendment. He was of opinion that the shortest and wisest way to deal with the whole concern was to appoint a Committee of Investigation thoroughly independent of the present Board; and he would therefore move an amendment:—

"*That a Committee of Investigation be appointed to inquire into the affairs of the Company, and to report to an adjourned meeting in four weeks' time.*"

Mr. RITCHIE seconded.

Mr. THORNE urged that his amendment should be put that the Report be not adopted till they had received a statement from the Chairman.

The CHAIRMAN: Well, gentlemen, in response to the invitation of Admiral Sir E. Inglefield, I rise to explain the disastrous balance-sheet, and the most disastrous state of the Company. I joined the Company in August last, and I took the chair in October last year. For the life of me I cannot say why I was asked to take the chair (laughter). The only motive I can think of was that the Board was anxious to get rid of a Director who had joined the Board, and they found it essential in the interests of the Company that that Director should be removed from his position (cries of "Name"). That gentleman failed to pay the calls on his shares, and the Directors availed themselves of the opportunity to declare his seat void at the Board. There are other little irregularities and other matters which I think—I regret to have to make these personal statements—should in the interests of the shareholders be looked to, and I at the risk and sacrifice of my own personal interests looked into them. I found that your money was being squandered in drink and refreshments. I found the most rotten state of things that could possibly be conceived in connection with a Company. I wish to deny all personal motives in saying what I do. My colleagues and I have acted together in the most harmonious way since Christmas, and made gigantic efforts to put the Company on a sound footing; but for obvious reasons—want of capital among them—our efforts have resulted in a most disastrous failure. The Report only goes up to December 31st. Up to that time practically no business had been done by the Company. Hence the lamentable result you see before you. Since Christmas we have done a considerable amount of work; but we have inherited from the old Company a heritage of litigation which has involved us in thousands of pounds outlay. With such an outlay and such limited capital you can imagine the poor prospect of the Company becoming a sound business concern. Before going any further I wish to warn the shareholders against any attempt made by people present to appoint a Committee of Investigation or a Committee of Inquiry. They would do no good. You are doomed to bankruptcy. No Committee of Inquiry can do you any good. Look the matter squarely in the face. We have a heritage of bad debts, and endless litigation from the old Company. We have spent thousands in litigation against Mr. Watt and the Brighton Corporation. Everything we touch seems to go wrong. The sums mentioned in the balance-sheet do not represent half of what we have spent since then (December 31st). Then there is the small capital. We had a capital of £13,000 or £14,000 subscribed to start the Company. I think my co-Directors will agree with me in saying it was a mistake ever to attempt to conduct any business whatever with that capital. I put it to you, was there ever any prospect for the Company under the circumstances which I have mentioned?

Mr. THORNE: What work has the Company done since December?

The CHAIRMAN: It has established an installation at St. Margaret's Mansions, which is a very valuable asset, looked at from that point of view. We have also lighted several flats in the Mansions. Altogether there are about 300 lights. We have lighted the Penny Bank there, and there is a long list of other works which I am ready to show to shareholders. We have also done work for Mr. Theobald, M.P., having lighted

Digitized by Google

his place, and given him great satisfaction ; and there are many other jobs which we could have taken had we had the capital in hand. I have, however, given my word that I will not be party to any more money being got out of the shareholders of this Company (hear, hear), and I must join issue with the *Financial News* when it says that in these days electric lighting companies are fairly established and are paying dividends. I ask the *Financial News* to name one electric lighting company that is paying a dividend.

A VOICE : Woodhouse and Rawson.

The CHAIRMAN : What is the dividend ?

The VOICE : 7½ per cent.

The CHAIRMAN : I understand from the Secretary that they have been in liquidation twice. Our difficulty is that we have to compete against men who have some knowledge of electricity, whereas the members of the Board have no practical experience of it. Those men render it impossible for any electric lighting company in the Kingdom to pay a farthing of dividend. I do not think that you will want me to go through the figures of the accounts. Altogether, it is a most disastrous state of things, and we shall not be able to get out of it with any number of Committees of Investigation. If I can reply to any questions I shall be happy to do so.

Dr. F. N. HAWKINS said that according to the Report a part of the business of that meeting was to elect Directors and auditors. How on earth, after the speech of the Chairman, they could be expected to do this he failed to understand. The Chairman had utterly ignored the future. He (the speaker) failed to understand how the Chairman could occupy the chair that day and speak as he had done of the prospects of electric lighting. Why, to listen to the Chairman, one would think it the only business in which there was any competition. Why had the Chairman said nothing about their future ? What do we want with Directors and auditors if it is only fit to wind up ?

The CHAIRMAN : You must have some machinery to wind up.

A VOICE : I move it be wound up.

The CHAIRMAN : You cannot appoint a liquidator to-day. That is a matter for a special meeting.

Dr. HAWKINS : What do you recommend should be done ?

The CHAIRMAN : Gentlemen, this is what I recommend. We have an action pending against Mr. Watt, and in your own interests I think that it would be well to entrust the business of the Company to the present Directors until that action is over. I think you ought not to let the Company fall into the hands of a few who are only interested in finishing it up. My advice is, trust your Directors, and do not be led away by clap-trap. Trust your Directors until this action is over.

Mr. HODGSON, in a lengthy speech, supported the Chairman's views.

A SHAREHOLDER asked when the action was likely to come on ?

The SOLICITOR hoped by the month of August. He doubted if it would be before the long vacation.

Mr. SPICER thought they could do with a far less expensive Board and management.

Mr. GRIFFITHS thought that if the Board would agree to forego their fees it would be a little guarantee of their desire to do well by the Company. When the shareholders were putting nothing into their pockets the Directors ought to be content to do without fees. Their pretensions would not seem so hollow if they would come to some compromise in this respect.

Mr. NEWTON felt the Board ought to be paid. It was not reasonable to ask men to work for nothing, but he regretted that the Board had gone to "loggerheads" amongst themselves. He was glad some of the Board had stuck to their posts.

The CHAIRMAN having explained, in reply to a shareholder, how it was that Mr Swaby received a total salary of £400, and having read the minute under which such payment was made,

Mr. MARKS entered into a very lengthy statement and found fault with many of the remarks and statements of the Chairman ; he alluded to the question of the removal of a Director, and said he did not know till that day that that was the reason the Chairman was elected on the Board. Then in the course of his address the Chairman had asserted that he had found that a large amount of money was squandered in drinks and refreshments. He wished to say that he had never had even a glass of bitter ale at the expense of the Company. The Chairman had also remarked that no business had been done up to December 31st. The volume of business was exceedingly small, but it amounted to £1,674. The remarks of the Chairman had taken him by surprise, and he did not agree with him at all, especially when he said they were doomed to bankruptcy. Dr. Hawkins had naturally asked, "Why on earth do you move resolutions for adoption of the Report and the re-election of Directors if the Company were doomed to bankruptcy." He (the speaker) did not think they were doomed to bankruptcy, and he was in favour of going into liquidation, or in favour of a Committee of Investigation. The course he suggested that the shareholders should adopt was for them to select gentlemen to fill up the vacancies on the Board. He suggested that course because new Directors would have more powers than a Committee of Investigation. Besides, they might appoint gentlemen who were hostile to the Company. So far as he was concerned he should welcome a Committee of Investigation, because the more they inquired into the affairs of the Company the more credit they would give them for the work they had done. What was the cause of their present position ? He would give them a statement of what had taken place. First of all they had to deal with the dissentient shareholders, which had occupied a great deal of their time. Then they had the Watt arbitration. Mr. Watt appeared on the register of the Company as the holder of 7,376 shares ; but the accountant, in going through the books, found that Mr. Watt held certificates for 4,416 shares which the Company had not issued. The Board declined to admit Mr. Watt's right to those shares, and the matter was referred to arbitration, Mr. Whinney being appointed arbitrator ; and he found that Mr. Watt was not entitled to the 4,416 shares. The unfortunate part of the matter was that Mr. Whinney only allowed them £50 for costs, and his own fee came to £48 (laughter). Then, again, they had some difficulty with Messrs. Crisps' account. Messrs. Crisps were indebted to them for £1,500, the payment of which account was refused, and a counterclaim put in for £2,000 for damage sustained by bad workmanship. The Board found that the agreement entered into with Messrs. Crisps showed that the work was to be done in adifferent manner, and they had been obliged ultimately to compromise the matter. When they had those facts before them, could they be surprised that they were not able to give proper attention to the ordinary affairs of the Company ?

The CHAIRMAN replied to Mr. Marks, and especially upon the question of drinks and refreshments. He did not assert that they had been had by the Board, but some one had had them. The petty cash book appalled him ; he found it ran to £10 per week (sensation), and he was told it was for drinks and refreshments at the Law Courts. The works manager (Mr. Tuff) told him so, and that it was customary in Mr. Watt's time ("Shame") There was no doubt those drinks were had.

Mr. TUFF (the works manager) said the refreshments were given to the men who worked late in lieu of overtime money.

The CHAIRMAN repeated that the money had been expended at the Law Courts.

Mr. KLENCK (depositing an enormous bundle of papers on the table) rose in an excited manner to address the meeting.

The CHAIRMAN pointed out that he was not qualified to speak, as he was neither a shareholder or Director.

Mr. NEWTON moved that Mr. Klenck should be heard, which was seconded ; but, after an acrimonious discussion, the motion was put and lost by an overwhelming majority.

Mr. KLENCK : Now I'll go on with my action sharp, then they will hear me.

The CHAIRMAN then put the motion for the adoption of the Report.

Mr. GUY moved an amendment for the appointment of a Committee of Investigation, which, however, was not seconded.

The original motion was then carried.

The retiring Directors were put up for re-election and approved, and Mr. Hodgson was added to the Board, Mr. Marks announcing that he should retire.

Admiral Inglefield was asked to return to a seat upon the Board. He, however, declined the honour, remarking that he had had more than enough of the Maxim-Weston Company.

The auditors were re-appointed at a fee of 30 guineas.

A SHAREHOLDER asked for another meeting before 12 months.

The CHAIRMAN said they would, he had no doubt, have another in less than six months, when the Watt action was settled.

A vote of thanks having been accorded to the Chairman, he, in returning thanks, said that he regretted he had not made the Company a success. The heritage of litigation and bad work clung to them. He was gratified that that day's meeting had been nothing like so disorderly as he had expected it would be.

The meeting then separated.

The Anglo-Portuguese Telephone Company (Limited).

The adjourned third ordinary general meeting of this Company was held yesterday at the offices, 53, New Broad-street; Sir Alexander Armstrong, K.C.B., F.R.S., presiding.

The SECRETARY (Mr. R. Rodgers) read the notice convening the meeting, and the Report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—In rising to move the adoption of the Directors' Report, I think the first thing I have to do is to congratulate the shareholders on the satisfactory state of the Company generally. There has been a steady increase of income and also of subscribers. The profit on the year's working amounts to £5,361. 16s. 8d. After deducting £600 paid for Debenture interest, and adding £5,827. 19s. 7d. brought forward from 1888, there remains a balance of £10,589. 16s. 3d. to the credit of profit and loss account. Out of this we have paid an interim dividend of 4 per cent., and it is now proposed to write off £1,500 discount on Debentures issued. This has been done by the advice of the auditors, as it cannot be considered an asset of the Company, the Debentures having been issued at a discount. We propose, after paying the interim dividend, to place £6,000 to reserve fund, leaving a balance of £1,089. 16s. 3d. to be carried forward to next year's account, which I think may be considered a very satisfactory state of the Company's affairs. The expenditure on capital account for the year has been large, £9,731. 13s. 10d. This outlay has been entailed in consequence of a great expense attending the erection of a new exchange at Santa Justa, and also because we were obliged to reconstruct many of the existing lines. Hence the expenditure appears large; but it will be gradually diminishing each successive year. The number of paying subscribers in Lisbon is 985, yielding a gross rental of £7,180; while in Oporto the subscribers number 870, giving a gross rental of £4,708, thus making a total income for the past year of £11,888, and showing a steady increase in subscribers of 222, and in value of £1,320 over the preceding year. I may further add that up to the 15th of April the income was £12,204; and since that date there has been a further increase of £316, so that the income at this moment stands at £12,520, which, considering the recent political disturbance in Portugal and the somewhat hostile feeling entertained towards every English enterprise in that country, we must consider satisfactory, and especially inasmuch as there has been no withdrawal of any subscribers except for good reasons. The affairs of the Company, therefore, as far as we can judge, appear to be in a promising state, with every indication of a steadily increasing business. In order to provide for further extensions, we took leave to issue £40,000 Eight per Cent. Second Mortgage Debentures, of which £10,000 were recently offered to subscribers in Portugal; and altogether we consider that this places the Company financially in a very satisfactory condition. There has been a retirement from the Lisbon Board of the Conde de Gouvea and of the Company's legal adviser in Portugal, Dr. Marcal Pacheco. With these few remarks I beg to move—

"*That the Directors' report and accounts ended December 31, 1889, as now presented, be received and adopted.*"

Mr. C. L. W. FITZGERALD seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. FITZGERALD, the retiring Directors, Mr. A. H. Baker and Senhor Jorge O'Neill, were re-elected to their seats at the Board.

The auditors, Messrs. Deloitte, Griffiths and Co., were also re-appointed, and the proceedings terminated.

NEW COMPANIES REGISTERED.

THORNEBURRY MINERS' SAFETY LAMP COMPANY (LIMITED).—This Company has been registered with a capital of £50,000 in £1 shares, to carry on the business, amongst other trades, of oil refiners and of china, glass, metal and general manufacturers, dealers and merchants of and in all apparatus and materials connected with the manufacture or use of lamps.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended May 2nd amounted to £4,596, and for May 9th to £2,896.

THE LEON COBALT AND COPPER MINING COMPANY (LIMITED).—Prospectuses will be issued to-morrow (Saturday), inviting subscriptions for the capital of a new Company, with the above title, formed to acquire and work valuable mining properties of cobalt and copper ore in Spain. The prospectus states that the properties cover an area of 859 acres, near the town of Villamanin. Mr. A. J. Beardmore, M.E., who has considerable knowledge of the districts in which the mines are situated, in reporting upon the property to be acquired by the Company, states that "the veins are numerous, and the Company has the run upon the lodes for a considerable distance. Rich deposits have invariably been met with, as in the case of 'The Tharsis and Rio Tinto,' as also in the cases of 'The Profunda' and 'The Providencia,' which adjoin the properties of the Leon Company, and are now being worked at a large profit, the ores being very rich, containing from 30 to 40 per cent. of copper and 5 per cent. of cobalt." Some specimens of copper taken from the property have been submitted for analysis, with the result that two specimens from the Company's largest group gave 24⅝ and 29¼ per cent. of copper respectively. A specimen of cobalt ore taken from another portion of the new Company's property, analysed by M. F. Claudet, gives—cobalt, 1·60; metallic copper, 0·37, showing that the ground is cobalt-bearing at a small depth. It may be mentioned that the present price of cobalt is about 8s. per lb. The consulting engineer of the Company is Mr. Edward Jones, M.E., of 4, Tokenhouse-yard, E.C. Some further particulars are given in our advertisement pages, and prospectuses and forms of application can be obtained to-morrow from the Company's bankers, the National Provincial Bank of England, 112, Bishopsgate-street, E.C.; from the brokers, Messrs. Derenburg and Co., 9, Drapers'-gardens, E.C.; and at the offices of the Company, 5, Throgmorton-avenue, London, E.C. The lists open on Saturday, and will close on or before Tuesday, the 20th inst. The shares were dealt in yesterday at a premium.

STOCK EXCHANGE.—Application has been made to the Committee to allow the following to be quoted in the official list:—United River Plate Telephone Company (Limited)—further issue of 3,000 shares, Nos. 55,001 to 58,000.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 2nd, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,515, and for the week ended May 9th, £2,085.

WREXHAM AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The first general meeting of this Company took place recently at the offices, No. 12, Queen-street, Wrexham, when an exhaustive report of the proceedings of the Directors since the registration of the Company and the present arrangements for the proposed works was read and adopted unanimously; as also the reports of the engineers engaged.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

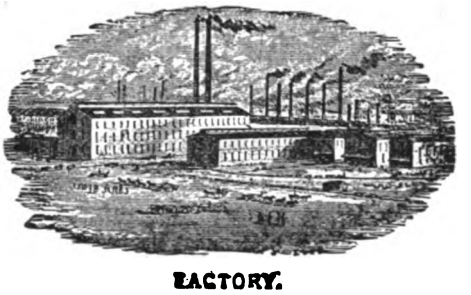
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-60in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 627.—Vol. XXV. FRIDAY, MAY 23, 1890. Price Fourpence.

NOTES.

The announcement which Major Cardew was able to make at the Institution of Electrical Engineers last Thursday that within the next two months a Government Standardising Laboratory on a small scale would commence operations, will be hailed with general satisfaction by the electrical profession. It is now close upon five years since Dr. Fleming first directed attention to this question in a brief but suggestive Paper before the Society of Telegraph Engineers and Electricians. Although the large scheme then sketched is as yet far from realisation, it must, we suppose, be considered a very satisfactory rate of progress for England that scarcely five years have elapsed between the sowing of the seed and the budding of the fruit. Within the next five years, therefore, we may reasonably hope to see a Government Electrical Standardising Laboratory arise, less grandiose but quite as useful as the many similar institutions on the Continent. By that time also the Board of Trade will probably have enlarged their electrical staff, so as to enable those responsible for this important work to devote their whole time to it. The first item on the programme is, we may add, the determination of the true values of the fundamental electrical units; and Major Cardew is hopeful that, with the assistance of Lord Rayleigh and the British Association Committee on Electrical Standards, these determinations will be of unimpeachable accuracy.

The Australasian Colonies have now an opportunity of proving whether their anxiety to reduce the cable rates is tempered with justice towards the Cable Companies. Sir John Pender, on behalf of the principal company concerned, has addressed a communication to the Agents-General of the Australasian Colonies, offering to reduce the rates by nearly one half for all classes of telegrams, provided the Colonies on their part will bear one half of any contingent loss sustained by that reduction, the companies bearing the other half. His proposal is to try the experiment for twelve months; and, if the result is encouraging, to extend the period on terms then to be agreed upon. But even if the arrangement is not extended the companies pledge themselves to establish a tariff not exceeding 8s. per word—against 9s. 4d., the present rate—provided the experiment shows that the companies will derive the same amount of revenue under the reduced tariff as they do under the present one. Nothing, it seems to us, could be fairer than this, or more honourable to the companies who thus voluntarily subject their traffic to a test which will be attended with considerable risk to them, but which cannot fail to benefit the Colonies whatever the result may be. If the Colonial Agents are so sure that reduced rates will prove remunerative here is a chance for them to back their opinion by promptly accepting Sir John Pender's offer.

The attempts which have been made from time to time to construct models illustrating the mechanical actions going on in a dielectric under the action of electric and magnetic forces have not been, as a rule, very successful. At the meeting of the Physical Society on Friday last, Lord Rayleigh exhibited a form of Huyghens' gearing, and showed how it might be made to illustrate the phenomena of mutual induction of electric circuits. The model is certainly the simplest illustration of these phenomena with which we are acquainted.

At the same meeting, Prof. S. P. Thompson described a most interesting series of experiments illustrative of the whole range of Koenig's classical researches on sound. It is a rare privilege to lecture on the life-work of any leader of science, and at the same time to have him present to demonstrate the experiments. No one could have been more happily chosen than Prof. Thompson for the purpose of rendering clear and vivid the intricate phenomena which had to be dealt with. The nature of beats and resultant tones, and the various influences contributing to the character or *timbre* of different sounds, were all fully illustrated in a wonderful series of experiments performed by Dr. Koenig himself with apparatus brought from his own laboratory. In the light of recent electrical researches the study of sound waves is of special interest, as the wave lengths dealt with are of the same order as those occurring in connection with electrical oscillations. In all probability many phenomena familiar to us from our sense of sound will serve to explain some of the more obscure effects arising from the interference and superposition of electrical waves.

The latest American device for the protection of electric lighting circuits from the effects of lightning is due to Mr. C. Wirt. It is well deserving of notice on account of its originality in principle, and also because it is simple in construction, is weatherproof, and requires no inspection. It consists of a pile of metal discs separated by thin ebonite washers. The upper disc is connected with the line by means of a central insulated bolt, and the lower disc goes to earth. The number of washers used will presumably depend on the tension employed in the circuit. In one form there are twenty ebonite gaps, whose

Digitized by Google

aggregate thickness does not exceed one-twentieth of an inch. The potential of the flash is sufficient to break down the successive gaps, and thus the lightning can get to earth. The real danger to the circuit, however, arises from the dynamo current maintaining the arc started by the flash, and this is ingeniously avoided by the method of construction adopted. The large masses of metal employed render the starting and maintenance of an arc difficult on account of their cooling effect; but, what is still more important, the dynamo current, in order to do any damage, must maintain several short arcs instead of one long one, and the number of gaps may be so adjusted that the potential needed to do this may far exceed any used in the lighting circuit. It will, however, be necessary to have sufficient thickness of insulation between the central bolt and the metal discs, or the flash will prefer to pass direct from the bolt to the lower disc, and the whole advantage claimed for the lightning guard will be lost. In the diagram which we have seen, the distance in question does not seem sufficiently great.

One of the many consequences of the general adoption of electric traction in the States will apparently be the disappearance, at no distant date, of the tramcar as at present known. Thus the ever progressive West End-street Railway Company of Boston is about to place cars on its lines having from two to three times the passenger-carrying capacity of the old horse cars. Heavier cars, combined with higher speeds, are in their turn bringing the question of more powerful brakes into prominence; and at Boston a Thomson-Houston electric "locomotive" equipped with a vacuum brake worked by a small motor, will shortly come into operation. Before long, in fact, the American tramways bid fair to fully justify their native appellation of "railways," since "trains" of two or three 60 passenger cars drawn by powerful electric locomotives running at a comparatively high speed will contribute their quota to the liveliness of transatlantic streets.

The New World is again to be called in to redress the balance of the old; this time in the matter of electrical nomenclature. At a meeting of the American Meteorological Society last month, it was unanimously resolved that in the naming of electrical units, the services which America had rendered to science had not been properly recognised, and the Society pledged itself to lend every assistance to the furtherance of the claims of Joseph Henry and Benjamin Franklin. At the meeting in question it was not decided what units should be allotted to these claimants. Mr. Francis B. Crocker, however, is of opinion that we should all soon be on speaking terms with the unit of self-induction if we could accustom ourselves to call it Henry, while Franklin, he thinks, might be allowed to appropriate the unit of specific inductive capacity; for "although Franklin knew nothing of inductive capacity, he knew fully as much as Watt knew of watts or Volta of volts." We do not wish in any way to deny these eminent men of science whatever immortality may be conferred upon their names by the decree of some future international electrical nomenclature committee. It will, however, be observed that any attempt to render these names monosyllabic like those of most of their *confrères* by the excision of the ultimate syllable will result in sounds suggestive of ideas quite other than electrical.

In another column will be found a very lively and characteristic account of the Telegraphers' Tournament, which was briefly noticed in our New York correspondent's letter three weeks ago, and on which we made some comments at the time. The description is contributed by Mr. P. B. Delany to the New York *Electrical Engineer*, and will be read with interest by telegraphists all the world over.

Barcelona.—Messrs. Siemens and Halske have applied for permission to erect a central station in Barcelona.

Social.—Sir John Pender entertained Mr. H. M. Stanley and a number of distinguished guests at dinner on Monday last at his house in Arlington-street.

The Tonquin and China Telegraphs.—Intelligence of the opening of the telegraph line connecting Tonquin with China by way of Yunnan has been received in Paris.

Oldenburg.—A company, consisting chiefly of influential manufacturers, has been formed to undertake the lighting of this town by electricity. £75,000 have already been subscribed.

Electric Traction in Italy.—*L'Elettricità* announces that the Board of Public Works has sanctioned the substitution of electricity for steam on the tramway from Firenze to San Domenico.

Birthday Honours.—Amongst the list of Queen's birthday honours we are pleased to note that the honour of knighthood has been conferred on the secretary to the Society of Arts, Mr. H. Trueman Wood.

Execution by Electricity.—The United States Supreme Court has refused the recent application for a writ of habeas corpus in the Kemmler case, but a "writ of error" was heard at Washington on Monday last.

Seizures of Accumulators in France.—In addition to its recent seizure of Laurent-Cély accumulators, the Société Française d'Accumulateurs Électriques has impounded some Julien and some Jarriant accumulators.

The Telephone in Melbourne.—The Australian papers state that shortly direct telephone communication will be established between the head quarters of the Melbourne and Suburban Fire Brigades' Association and every suburb.

Electric Lighting Activity in the West End.—The Highways Committee of the London Council reported on Tuesday that there were applications for the laying of mains in no less than 152 streets, all west of the Law Courts.

Electric Traction.—Several members of the Glasgow Corporation have paid a visit of inspection to the electric tram-cars of the North Metropolitan Tramways Company. They expressed themselves much pleased with what they saw.

Royal Society.—Among the Papers down for reading at the Royal Society yesterday was one "On a Method of Determining the Value of Rapid Variations of a Difference of Potential by means of the Capillary Electrometer," by Mr. G. J. Burch.

Barnsley.—At a meeting of the Town Council, on Tuesday, it was decided that Mr. Bromley Holmes, manager of the Liverpool Electric Supply Company, should be called in to advise and report to the Council upon the tenders submitted for lighting the town by electricity.

The Electric Welding of Shells.—According to *Modern Light and Heat* the United States Government has already given an order for 100,000 shells for the Hotchkiss gun and Shrapnell shells, to be manufactured under the electric welding patent of Lieut. Wood, U.S.N., to which we referred in our issue of May 2nd.

The Swan Patent in Germany.—The two patent suits in Berlin between the Allgemeine Electricitäts Gesellschaft and agents of the Swan Company have been decided in favour

Digitized by Google

of the Swan agents. The third suit between the Swan Company itself and the Allgemeine Electricitäts Gesellschaft has not yet been decided.

Silver Bronze.—In a paper recently read before the American Institute of Mining Engineers, Mr. E. H. Cowles described a new high resistance alloy called "silver bronze," which he proposed as a substitute for German silver. Its composition is as follows: Manganese 18, aluminium 1·2, silicium 5, zinc 13, copper 67·6.

Paddington Vestry.—At a meeting of this Vestry, on Tuesday, the Vestry's solicitor was instructed to withdraw the opposition to the application of the Metropolitan Electric Supply Company for a Provisional Order. Some technical objections are, however, taken to these proceedings, and there is to be a meeting on the 29th inst., at which a formal decision will be arrived at.

The Electro-Motor Electrical Works.—At the Heaton Works of Messrs. C. A. Parsons and Co., the whole of the machinery has now for some time past been run by an electro-motor, the current for which is obtained from dynamo machines and engines that are running for test purposes, and the exhaust steam of which is employed to heat the shops. The economy of this arrangement is obvious.

L'Elettricita.—The editor of *l'Elettricità* informs us that he has received a large number of replies in answer to the two questions recently propounded by him. (See *The Electrician*, April 4th.) There was a general consensus of opinion that Hertz's investigations were the most important of recent years, but opinions differed considerably as to what application of electricity would make the greatest progress during 1890.

The Italian Edison Company.—This Company shows a net profit for 1889 of 205,463 lire (£5,125). The principal station at Milan had at the close of the year 565 arcs and 14,807 incandescents at work. This year additional plants are to be put down at Florence, Parma, and the Tarenti Arsenal; and negotiations for a station at Venice are pending. The Company has also taken over the Risalto factory for making electric apparatus.

The Renard Battery and Aerial Navigation.—According to *La Lumière Electrique* Commander Renard's light batteries are not likely to prove of much use for the purpose for which they were mainly designed, namely, aerial navigation. Our contemporary estimates that to maintain a moderately sized balloon in a stationary position for one hour against a breeze of average strength, one ton of Renard batteries would be required.

The Frankfort Exhibition, 1891.—In connection with this Exhibition, some particulars of which will be found in our advertising columns, we understand that it is the intention of the Oerlikon Maschinenfabrik, in conjunction with Messrs. Escher, Wyse, and Co., of Zürich, to equip an electric launch capable of carrying a hundred persons, which it is proposed shall travel up and down the nearest waterways in the interests of the Exhibition. It is also proposed to hold an International Electrical Congress during the Exhibition.

Koenigsberg.—The following are some additional particulars with regard to the municipal central lighting station at Koenigsberg, which, as we mentioned some time ago, is to be worked on the five-wire system. The steam plant comprises two pairs of triple-expansion engines of 100 and 200 horse-power respectively, coupled direct to the dynamos, which are eight in number. The mains are run underground in Monier conduits, and a large battery of Tudor accumulators assists in the supply. This station will shortly come into operation.

Southend.—The Southend Local Board, by a majority of one, have decided to erect works for electric lighting and traction at the new pier; and Messrs. Crompton and Co. have already sent in an estimate for the work. Mr. Watson Smith, resident at Southend, and a representative of Messrs. E. P. Elieson and Smith, has, however, informed the Board, as a ratepayer, that Messrs. Crompton's tender is too high; and in consequence of this the Board have not as yet decided what steps to take in carrying the resolution into effect. Messrs. Crompton's tender involved a total expenditure of about £5,500.

Cardiff.—At the last meeting of the Lighting Committee of the Town Council, a letter was read from the Brush Electrical Engineering Company, asking the Corporation to give its consent to the Company's proposed Provisional Order, and stating that, in the event of the Corporation deciding to obtain its own order, the Brush Company would be prepared to carry out the necessary work. It was resolved that no deputation should be received from the Brush Company until the Committee had decided whether it would recommend the Corporation to go for a Provisional Order, and that a special meeting of the Committee should be called to consider the question of recommending the Corporation to do so.

The Penny Post Jubilee.—At the *conversazione* given at the Guildhall last week by the Corporation in celebration of the Jubilee of the Penny Post, the telegraphic exhibits attracted great attention. The historical exhibits included Cooke and Wheatstone's four-needle telegraph of 1838, and also their double-needle telegraph. The Exchange Telegraph Company showed their column-printing telegraph in operation. Amongst the Post-Office apparatus being manipulated were Morse sounders, working to Penzance; Morse sounders working duplex to Manchester; the Hughes type-printing telegraph, connected with Paris and Berlin; and the Wheatstone automatic. Quadruplex and multiplex working was also shown.

The Halifax-Bermudas Cable.—The steamship "Westmeath," with the Halifax-Bermudas cable on board, left the Thames yesterday afternoon. Capt. A. W. Stiffe will be in charge of the cable-laying operations, and it is expected that telegraphic communication between the two important naval stations of Halifax and Bermuda will be established within the next month or so. The total length of the cable is 874 knots, and its total weight is about 2,000 tons. The Halifax shore end weighs 9·4 tons to the milet. The Bermuda shore end, owing to the presence of coral reefs, has been made especially heavy, and weighs about 19 tons to the mile. The cable, which was manufactured for the Halifax and Bermudas Cable Company by W. T. Henley's Telegraph Works Company, was thoroughly tested before shipment by the Post Office authorities, who pronounced it satisfactory. On Wednesday afternoon Sir Alexander Armstrong, K.C.B. (Chairman), and the Directors of the Halifax and Bermudas Cable Company, with others interested in the success of the Company, went down by special steamer to inspect the "Westmeath" at Greenhithe. We may add that the contractors, Messrs. W. T. Henley's Telegraph Works Company, are just proceeding with the manufacture of another submarine telegraph cable, about 1,000 miles in length.

The Telegraph Conference.—The details of International Telegraphy are regulated by a Conference of delegates appointed by all the Administrations interested, which meets every five years. The last Conference having taken place in 1885 the representatives of the different Governments and of the private companies, mostly submarine, interested in telegraphy, assembled at Paris on May 16th, in the Salle de Manege of the Louvre, when they were addressed by M. Roche, the Minister of Commerce and Industry. Afterwards two Commissions were appointed, one to consider the rules, and the other the tariffs. These have already had several meetings, and amongst other matters it has been decided to adjourn the German proposition, for an uniform rate in Europe of twopence per word, until the next Conference some five or seven years hence. It does not seem to be generally known that all but three or four of the European States lose money by their telegraphs, and had the German proposal been carried this deficit would have been largely increased, while its effect upon the revenues of the Cable Companies would have been almost disastrous. Several other important matters have yet to be discussed, but it is satisfactory to find that the representatives of the Governments recognise the services rendered by the Companies, and show a willingness to arrange the tariff in such a manner that their revenues shall not suffer to any serious extent.

The Telephone in Germany.—According to *Uhlands Wochenschrift* there were in Germany on October 1, 1889, no less than 179 towns with telephone exchanges. There were at the same date 39,876 telephones in use connected by 57,505 kilometres of wire; the average number of communications per diem being 581,839. The following is a list of the towns connected

Digitized by Google

by trunk wires, together with the average number of communications exchanged during a day of twelve hours :—

	Kilom.	Communications.
Berlin-Hamburg	290	194
Berlin-Brunswick-Hanover	528	24
Berlin-Magdeburg	177	39
Berlin-Stettin	177	26

Hamburg-Kiel	95	30
Kiel-Flensburg	122	12
Leipzig-Meeran	65	45

A New Toepler-Holtz Influence Machine.—A new form of the Toepler-Holtz machine has just been brought out by Queen and Co., of Philadelphia. The machine, says the *Scientific American*, is a three-plate machine. The third plate is a perfectly plain glass plate, mounted upon the same axis as the usual revolving plate, and placed behind the fixed plate. Its *modus operandi* is, like many other points in the theory of the Holtz machines, not entirely understood, although there is no doubt but that much of the increased efficiency obtained by its use is due to the screening effect it has upon the other plates; there is also supposed to be a considerable generation of electricity by friction of the plain plate and the air. The advantage of this new form of machine becomes especially marked during moist weather. Another improvement is the form of the electrode which is used. This consists of a metallic disc 2in. or more in diameter, and hollow, so as to have very gradually rounded edges, this preventing any leakage at the edges. Over this disc, separated from it by about $\frac{1}{8}$in., and nearer the other electrode, is fastened a thin disc of vulcanised rubber about $\frac{1}{2}$in. less in diameter. This rubber disc plays the part of the rubber sheet sometimes held between the electrodes, and compels a much higher potential to be established between the two electrodes before a spark can pass. It can be used upon either one or both electrodes, as desired.

An Electric Acoumeter.—With a view of preventing fraud on the part of those who have been drawn for military service, and with whom partial deafness is a very common plea for exemption, Dr. V. Cheval, of Brussels, has brought out a modification of Prof. Hughes's sonometer, which he calls an electric acoumeter. The apparatus consists of three flat coils placed parallel to one another on a graduated rod passing through their axes. The centre coil is the primary and is fixed, the two outer coils are secondaries, and can be slid along the rod. The rod and coils are arranged on a board, on which there are an electrical tuning-fork, a microphone, switches, plugs, and other accessories. The individual whose hearing is to be tested is placed with his back to the apparatus, and has two telephonic receivers fixed tightly over his ears. Various sounds are then produced; the two outer coils being moved gradually away from the centre one until no noise is heard in the telephone receivers. The distance through which the coils have been moved is a measure of the hearing power of the individual. According to Dr. Cheval's investigations a person gifted with a fine sense of hearing ceases to hear the telephonic vibrations of a tuning fork on the left side when the coil is 435mm. distant, and on the right side when the coil has been moved through 535mm. For less sensitive ears the distances are respectively 293 and 401mm. Deafness sufficiently pronounced to exempt from military service is represented by a distance of 100mm. These distances, of course, are not absolute, and only refer to the particular apparatus employed in these researches.

The Electrical "Ageing" of Alcohol.—After the crude material has been obtained, there are two stages in the process of preparing alcohol, namely, the rectification and the ageing. The method usually adopted for the latter purpose is to allow the spirit to remain several years in badly-corked barrels. This naturally involves the storage of large quantities of spirit, and to overcome this disadvantage M. Teillard has adopted the Broyer-Petit electro-chemical method at his distillery at Tournus. The principle of this process is to hasten the oxidation of the alcohol by exposing it to the action of ozone. To prepare the ozone two spirals of aluminium are arranged, one outside and one inside a perforated glass tube 1cm. in diameter and 45 cm. long; around this tube is another one. The ends of the two spirals pass through the outer tube, and are connected to the terminals of an induction coil. Oxygen is sent through the inner tube, and is exposed to the influence of a silent discharge between the two spirals. Great care is required in this operation. No sparks must occur, and the temperature of the apparatus must not exceed 15° to 20° C., or the ozone will be destroyed. In actual practice the oxygen is passed through three such tubes in succession, the induction coils being worked by a dynamo giving 3 volts and 6 amperes. By this means 10 cubic ms. (353 cubic feet) of oxygen is ozonised per hour. In addition to the dynamo, engine, and boiler, the complete installation comprises an oxygen gasometer of 20 cubic ms. capacity, six spirit vats, an oxygen pump, and an alcohol pump. All taps must be of wood, all tubes of glass, all plugs of cork, and the interior of the vats completely stripped of metal, owing to the energetic action of the ozone. In carrying out the process six vats are first filled with spirit. Oxygen is then passed from the gasometer over chloride of calcium to dry it, and is then passed through the ozonisers to a flask with three tubulatures, and thence through the six vats in succession to the condenser, where any vapour of alcohol taken up is deposited. The gas is then regenerated and used afresh. The volume of ozone required is about six times the volume of the alcohol treated, and the time required varies from five to six hours. Alcohol so treated is then stored in barrels, and after five or six months is ready for use.

The Keswick Water-power Electric Light Station.—At the last meeting of the Institution of Civil Engineers a Paper, by Messrs. W. P. James Fawcus and Edw. W. Cowan, was read on this the first attempt to utilise water-power in this country for the purposes of a public supply of electric light. The alternating-current transformer system is employed, and the station is on the banks of the River Greta, about three-quarters of a mile from Keswick, where there is a head of 20ft. The rent paid for the water is 10s. per horse-power per annum. Taking the number of horse-power hours required per annum as 100,000 for the present output of the station from a 50 horse-power turbine, the cost per horse-power came out as 0·06d. On the other hand, taking the price of steam coal at 15s. per ton, and the quantity burnt per horse-power per hour as 6lb., the cost per horse-power hour came to 0·48d. As there is, however, a possibility of partial failure of the water-supply during extreme drought in summer, steam is provided in addition. The turbine is a "Victor," of a mixed-flow type; the wheel is 20in. in diameter, and its speed is 273 revolutions per minute. The engine is a Westinghouse of simple type, having two single-acting cylinders, 10in. diameter by 9in. stroke; at 350 revolutions per minute, with 80lb. of steam, it gives 50·11 B.H.P. The alternator, designed by Mr. Gisbert Kapp, and manufactured by Messrs. Johnson and Phillips, the contractors for the electrical plant, is a 30-kilowatt (15 amperes 2,000 volts) machine. It runs at 750 revolutions, and the frequency is 75. The resistance of the armature, after working some hours, has been found to be 7 ohms. The total resistance of the field, after working some hours, is 11·2 ohms. The mains are carried overhead, and special attention has been paid to obtaining good insulation at the supports by means of oil insulators. The sizes of the mains are fixed for a current density of 500 amperes to the square inch. The fall of potential between the generating station and the town is only slightly above 1 per cent at full load. Steel suspension strand is used for supporting the mains for all circuits. One short run of underground mains on the Brooks fluid system is being tried. A series of experiments have been made to test the efficiency of the machinery, with the result that the total efficiency of the generating plant at the station came out at about 40 per cent. at $\frac{1}{4}$ full load, and over 70 per cent. at full load.

MAGNETISM IN IRON AND OTHER METALS.*—XVIII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 31.*)

§ 78. **Effects of Hysteresis.**—Figs. 43 and 44 give further illustrations of the effects of magnetic hysteresis in causing loops to be formed on the curves of magnetisation when the magnetising force experiences any cyclic change. Fig. 43 refers to a ballistic test of a ring of very soft annealed iron. It shows, in addition to the large loop produced by reversal of the magnetising force, a smaller loop produced by its removal and re-application, and also two small loops formed by pausing at points on the steep part of the demagnetisation

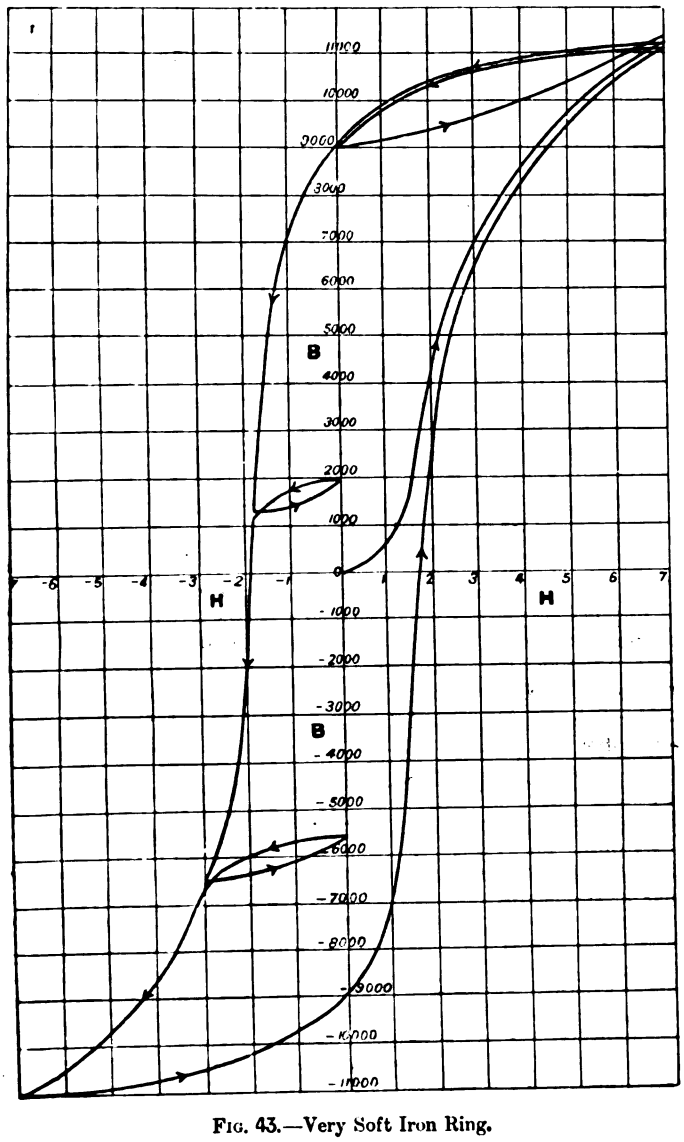

FIG. 43.—Very Soft Iron Ring.

curve and removing and re-applying the force there. In Fig. 44 the effects are shown of removing and re-applying the force at a number of successive points during the magnetisation of a long wire of soft annealed iron. Many of the experiments have shown that similar loops are formed by partial instead of complete withdrawal of magnetising force, followed its re-application, and that steel, nickel, and cobalt yield results of the same kind. The form of the curves is found to be not materially different whether the changes of magnetising force are made to occur at a moderate rate or excessively slowly. In other words, the hysteresis shown by these loops is persistent with regard to time. Even prolonged pauses, during which the magnetising force is kept constant at values midway between the two extremes of the cycle, do not cause the differences of magnetism due to hysteresis to disappear, or even to become sensibly lessened.

It is at the steep parts of the magnetisation curve that the effects of hysteresis are most apparent. Starting from a point such as a (Fig. 44), removal and re-application of the force augment the magnetism; this is because the acquisition of magnetism in the original ascending process was retarded by hysteresis, with the result that any species of disturbance (such as the renewal and re-application of the force) causes an increase. If we were to repeat the cyclic disturbance by again removing and re-applying the same force, we should find a small further increase; and it is only after several repetitions of the cycle of magnetising force that its magnetic effects become strictly cyclic.

Every loop in these diagrams shows that whenever the process of altering the magnetic force is reversed from a process of increment to a process of decrement, or *vice versâ*, the magnetism begins to change very slowly relatively to the change of **H**, no matter how fast it may have been changing (in the opposite direction) immediately before. So much is this the case that the curves, when drawn to a scale so small as the scale of these diagrams, appear to start off tangent to the horizontal line whenever the change of **H** is reversed in sign. It will be shown, however, in a later chapter that the initial gradient

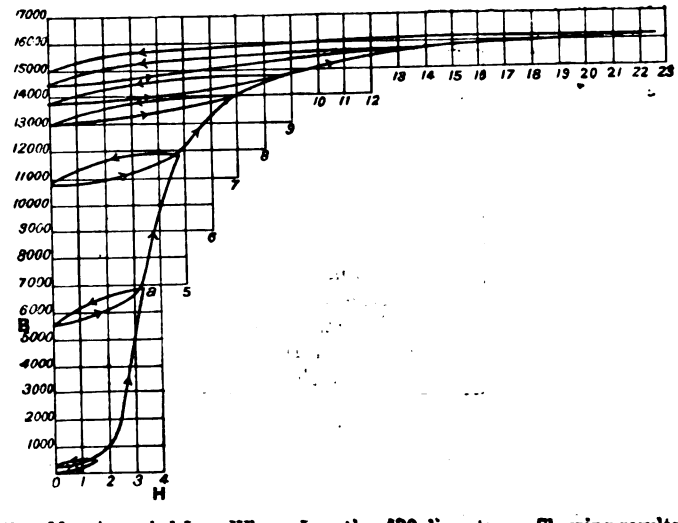

FIG. 44.—Annealed Iron Wire. Length = 480 diameters. Showing results of removing and reapplying the magnetising force.

of these curves is not really zero, but a small positive quantity. At the steepest part of the great cycle in Fig. 43 the value of $\frac{d\mathbf{B}}{d\mathbf{H}}$ is no less than 14,500; in the initial slope of one of the small loops $\frac{d\mathbf{B}}{d\mathbf{H}}$ is probably not more than 150. In other words, if during the reversal of magnetism we pause at the steepest part of the curve and begin to remove the magnetic force, the gradient of the new curve is about 100 times less steep than that of the curve from which it springs.

An obvious effect of hysteresis is to prevent any simple relation from existing between **H** and **B**, or **H** and **I**. To specify the magnetisation, we must know not only what value the magnetic force actually has, but what changes it has undergone in reaching that value. Associated with any one value of the force there is a wide range of possible values of **B** or of **I**. By a suitable choice of processes in the application and removal of **H**, we may carry the magnetisation curve through any point whatever within the wide area enclosed between the curves which correspond to reversal and re-reversal of a strong magnetising force. Hence the definition of permeability, as the ratio of **B** to **H**, or the definition of susceptibility, as the ratio of **I** to **H** requires to be limited (as was indicated in § 21) by the conditions (1) that the piece is neutral to begin with; and (2) that the magnetising force, with reference to which the permeability or susceptibility is expressed, is to be applied by simple increment from zero, without passing at any stage from higher to lower values

* All rights are reserved.

Digitized by Google

Not only may the magnetisation curve be made to pass through any specified point in the area enclosed by the large reversal curves, but it may have more than one gradient in passing through the point. The following is an interesting example of this effect of hysteresis. Suppose that on the descending limb, P Q, of the main reversal cycle we have stopped increasing the negative magnetic force at a point Q, so chosen that when the force is removed the curve Q O passes through the origin. When the process Q O is completed, the piece has no magnetism, and it lies in a field of no force. Tested in any ordinary way it might seem to be in a perfectly neutral state; but its condition is far from being the same as that of a virgin piece, or from that of a piece which has been made neutral by the process of "demagnetising by reversals." Such pieces show no directional difference; their susceptibility is the same whether the first magnetising force be positive or negative. But in this case a positive force would give the curve O R, which is a continuation of Q O; whereas a negative force would give the wholly different curve O S. The initial susceptibility in the former case is very much greater than in the latter. In consequence of hysteresis the piece, although destitute of actual magnetism and not acted on by any magnetising force, retains traces of the magnetic changes it has passed through, which cause it to show a striking want of directional symmetry when it is subsequently magnetised in one or the other direction.

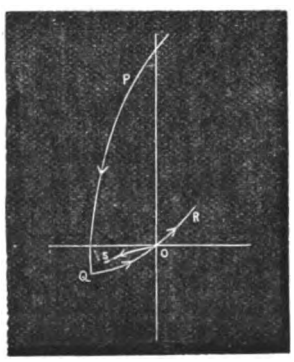

Fig. 45.

Though there is no external evidence that the piece is anything but neutral, it is much more ready to take magnetism of an opposite sign from that which it last held than to take magnetism of the same sign.

(To be continued.)

ON PROF. ELIHU THOMSON'S ELECTRO-MAGNETIC INDUCTION EXPERIMENTS.*

By J. A. Fleming, M.A., D.Sc., M.I.E.E., Professor of Electrical Engineering in University College, London.

(Continued from page 35.)

We have already seen that in an alternating field the electro-dynamic impulses so experienced by the disc or ring are alternately attractive and impulsive, and that when the circuit possesses a sensible self-induction, the repulsive impulses overpower the attractive ones, and their repetition constitutes a repulsive force. Before adding a few more words of explanation, permit me to show you some of these electro-dynamic repulsions produced by an alternating electro-magnet. Here is a copper ring, and I lay it upon the top of this electro-magnet, having a divided iron core and excited by a powerful alternating current. On energising the magnet the ring jumps up in the air (*see* Fig. 9). If a copper plate is hung like a scale pan from a balanced beam, and placed over the magnetic pole, it gives evidence of being strongly repelled the moment we pass the current through the coils of the magnet (*see* Fig. 10). Instead of employing copper rings or copper plates, we can use closed coils of thick wire, either insulated or not. If, however, our plates or rings have a radial slit made in them, or if our coils of wire are not closed-circuit coils, all the effects vanish.

So strong is this repulsion with proper appliances, that light copper rings tethered by strings may be held suspended in the air against the force of gravity, the upward electro-magnetic repulsion overcoming their weight, and holding them, like Mahomet's fabled coffin, floating in the air (*see* Fig. 11). In cases where we are dealing only with impulsive effects, aluminium rings or discs give most marked results, because aluminium has the highest conductivity per unit of mass; but in the cases like those just considered, where what is required is the greatest force effect, copper or silver gives a better

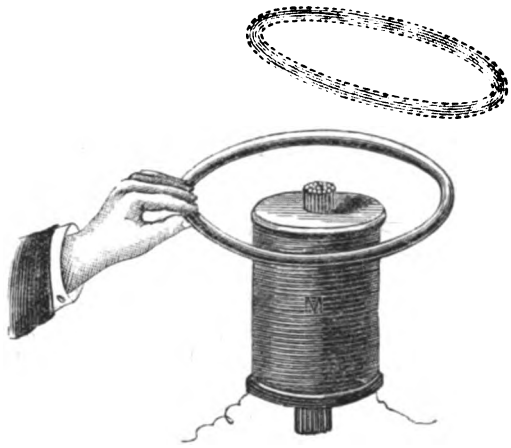

Fig. 9.

result than aluminium, because they have the highest conductivity per unit of volume. In Mr. Boys' experiments, if I remember rightly, he found aluminium the best to employ. In these cases of

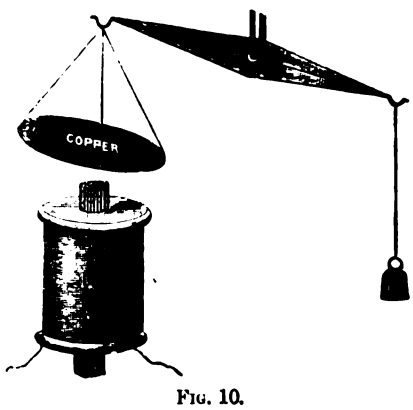

Fig. 10.

electro-dynamic repulsion the force effect depends essentially upon the lag of the induced current or its retardation in phase behind that of the inducing field, and, other things being equal, this is

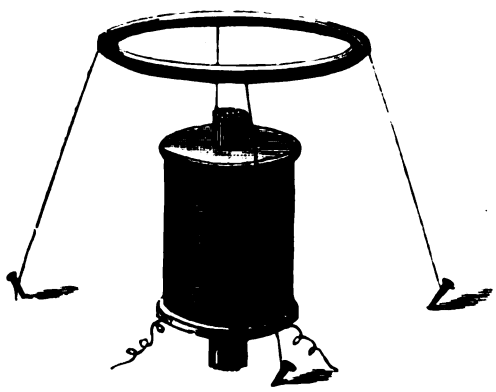

Fig. 11.

proportional to the conductivity of the circuit. I will pass before your view a series of diagrams intended to represent various cases and modes of production of these repulsive effects, giving you descriptions of them in Prof. Elihu Thomson's own words. He says:—

"This preponderating repulsive effect may be utilised or may show its presence by producing movement or pressure in a given

* A Paper read before the Society of Arts, May 14, 1890.

Digitized by Google

direction, by producing angular deflection as of a pivoted body, or by producing continuous rotation in a properly organised structure.

"In Fig. 12, C is a coil traversed by alternating currents, B is a copper case or tube surrounding it, but not exactly over its centre. The copper tube B is fairly massive and is the seat of heavy induced currents. There is a preponderance of repulsive action tending to force the two conductors apart in an axial line. The part B may be replaced by concentric tubes slid one in the other, or by a pile of flat rings, or by a closed coil of coarse or fine wire insulated or not. If the coil C, or primary coil, is provided with

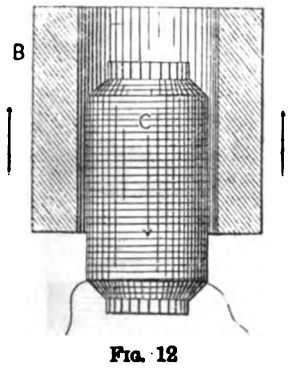

FIG. 12

an iron core such as a bundle of fine iron wires, the effects are greatly increased in intensity, and the repulsion with a strong primary current may become quite vigorous, many pounds of thrust being producible by apparatus of quite moderate size.

"The forms and relations of the two parts C and B may be greatly modified, with the general result of a preponderance of repulsive action when the alternating currents circulate.

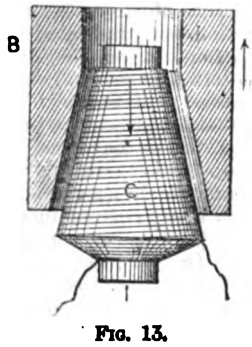

FIG. 13.

"Fig. 13 shows the part, B, of an internally tapered or coned form, and C, of an externally coned form, wound on an iron wire bundle, I. The action in Fig. 12 may be said to be analogous to that of a plain solenoid with its core, except that repulsion, and not attraction, is produced, while that of Fig. 13 is more like the action of tapered or conically-wound solenoids and taper cores. Of course, it is unnecessary that both be tapered. The effect of such shaping is simply to modify the range of action and the amount of repulsive effort existing at different parts of the range.

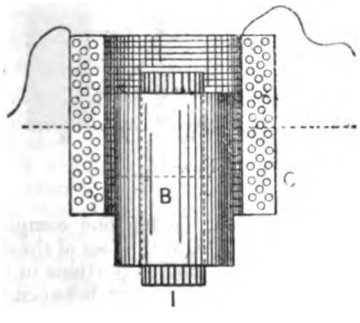

FIG. 14.

"In Fig. 14 the arrangement is modified so that the coil C is outside, and the closed band or circuit B inside and around the core I. Electro-inductive repulsion is produced as before.

"It will be evident that the repulsive actions will not be mechanically manifested by axial movement or effort, when the electrical middles of the coils or circuits are coincident. In cylindrical coils, in which the current is uniformly distributed through all the parts of the conductor section, what I here term the electrical middle, or the centre of gravity of the ampere turns of the coils, will be the plane at right angles to its axis at its middle, that of B and C in Fig. 14 being indicated by a dotted line. To repeat, then, when the centres or centre planes of the conductors, Fig. 14 coincide, no indication of electro-inductive repulsion is given, because it is mutually balanced in all directions; but when the coils are displaced, a repulsion is manifested, which reaches a maximum at a position depending on the peculiarities of proportion and distribution of current at any time in the two circuits or conductors.

"In Fig. 15, B represents a copper ring, and C an annular coil placed parallel thereto; and an iron core or wire bundle placed in

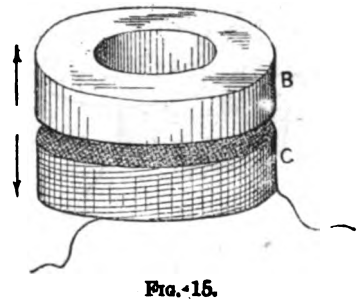

FIG. 15.

the common axis of the two coils shows the repulsive action when an alternating current is passed through C. B may be simply a disc or plate of any form, without greatly affecting the nature of the action produced. It may also be composed of a pile of copper washers or a coil of wire, as before indicated.

"An arrangement of parts somewhat analogous to that of a horseshoe electro-magnet and armature is shown in Fig. 16. The alternating-current coils C C′ are wound upon an iron wire bundle

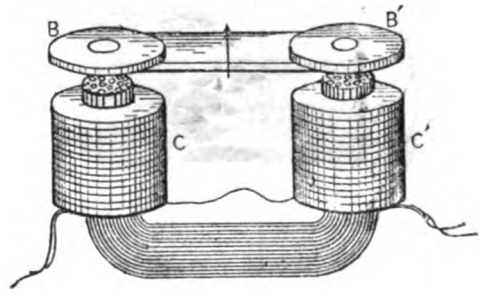

FIG. 16.

bent into U-form, and opposite its poles is placed a pair of thick copper discs, B B′, which are attracted and repelled, but with an excess of repulsion depending on their form, thickness, &c.

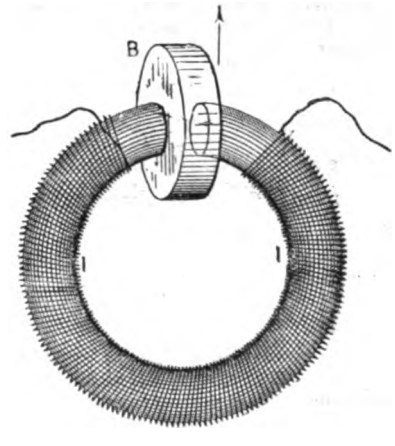

FIG. 17.

"If the iron core takes the form of that shown by I I, Fig. 17, such as a cut ring with the coil C wound thereon, the insertion of a heavy copper plate, B, into the slot or divided portion of the ring will be opposed by a repulsive effort when alternating currents pass in C. This was the first form of device in which I noticed the

Digitized by Google

phenomenon of repulsive preponderance in question. The tendency is to thrust the plate B out of the slot in the ring, excepting only when its centre is coincident with the magnetic axis joining the poles of the ring between which B is placed.

"If the axes of the conductors, Fig. 15, are not coincident, but displaced, as in Fig. 18, then, besides a simple repulsion apart, there is a lateral component or tendency as indicated by the arrows. Akin to this is the experiment illustrated in Fig. 19. Here the closed conductor B is placed with its plane at right angles to that of C, wound on a wire bundle. The part B tends to move toward the centre of the coil C, so that its axis will be in the middle plane of C, traverse to the core, as indicated by the dotted line. This leads us at once to another class of actions, *i.e.*, deflective actions.

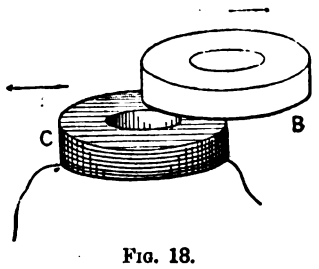

FIG. 18.

"When one of the conductors, as B, Fig. 20, is comp sed of a disc, or, better, of a pile of thin copper discs, or of a closed coil of wire, is mounted on an axis X transverse to the axis of coil C, through which coil the alternating current passes, a deflection of B to the position indicated by dotted lines will take place, unless the plane of B is at the start exactly coincident with that of C. If slightly

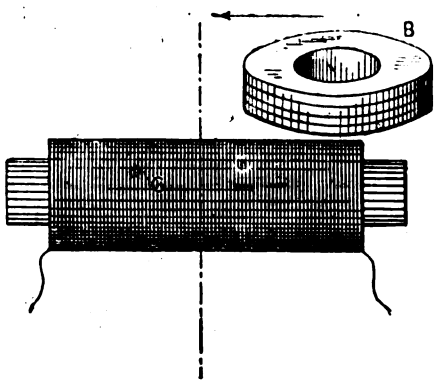

FIG. 19.

inclined at the start, deflection will be caused as stated. It matters not whether the coil C incloses the part B or be inclosed by it, or whether the coil C be pivoted and B fixed, or both be pivoted. In Fig. 21 the coil C surrounds an iron wire core and B is pivoted above it as shown. It is deflected, as before, to the position indicated in dotted lines.*

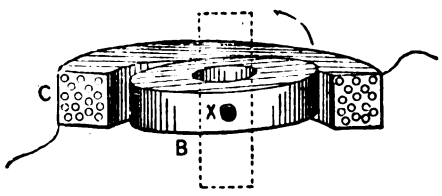

FIG. 20.

"It is important to remark here that, in cases where deflection are to be obtained as in Figs. 20 and 21, B had best be made of a pile of thin washers or a closed coil of insulated wire, instead of a solid ring. This avoids the lessening of effect which would come from the induction of currents in the ring B in other directions than parallel to its circumference."

* This deflection by an alternating current of a copper disc suspended within a coil with its plane inclined to the plane of the coils I myself noticed independently in March, 1887, and subsequently described a copper disc galvanoscope for alternating currents based on this fact (see *The Electrician*, May 6, 1887). I did not at the time know how thoroughly Prof. Thomson had explored the phenomena, but the substantial explanation of it had already occurred to me.

Returning for a moment to the theory of these repulsive and deflective actions, it will repay us to consider it in the form placed before us by Prof. Thomson, in his first Paper on the subject, read before the American Institute of Electrical Engineers, May 18, 1887. He says:—"It may be stated as certainly true that were the induced currents in the closed conductor unaffected by any self-induction, the only phenomena exhibited would be alternate equal attractions and repulsions, because currents would be induced in opposite directions to that of the primary current when the latter current was changing from zero to maximum positive or negative current, so producing repulsion; and would be induced in the same direction when changing from maximum positive or negative value to zero, so producing attraction.

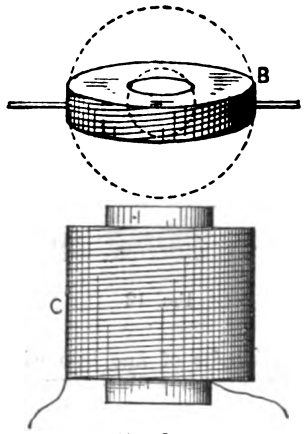

FIG. 21

"This condition can be illustrated by a diagram, Fig. 22. Here the lines of zero current are the horizontal straight lines. The wavy lines represent the variations of current strength in each conductor, the current in one direction being indicated by that portion of the curve above the zero line, and in the other direction by that portion below it. The vertical dotted lines simply mark off corresponding portions of phase or succession of times.

"Here it will be seen that in the positive primary current descending from m, its maximum, to the zero line, the secondary current has risen from its zero to m^1, its maximum. Attraction will therefore ensue, for the currents are in the same direction in the two conductors. When the primary current increases from zero to its negative maximum n, the positive current in the secondary closed circuit will be decreasing from m^1, its positive maximum, to zero; but, as the currents are in opposite directions, repulsion will occur. These actions of attraction and repulsion will be reproduced continually, there being a repulsion, then an attraction, then a repul-

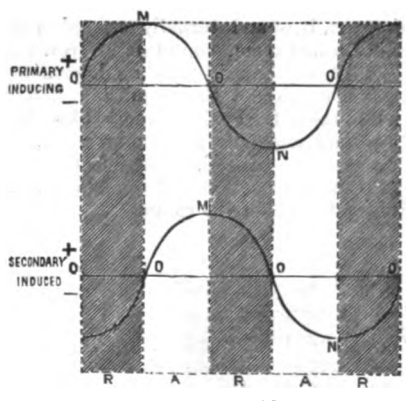

FIG. 22.

sion, and again an attraction, during one complete wave of the primary current. The letters r, a, at the foot of the diagram, Fig. 22, indicate this succession. (The shaded portions in the diagrams represent the time during which the force between the primary and secondary circuits is a repulsive force.)

"In reality, however, the effects of self-induction in causing a lag, shift, or retardation of phase in the secondary current, will considerably modify the results, and especially so when the secondary conductor is constructed so as to give to such self-induction a large value. In other words, the maxima of the primary or inducing current will no longer be found coincident with the zero points of the secondary currents. The effect will be the same as if the line representing the wave of the secondary current in Fig. 22 had

Digitized by Google

been shifted forward to a greater or less extent. This is indicated in diagram, Fig. 23. It gives, doubtless, an exaggerated view of the action, though from the effects of repulsion which I have produced I should say it is by no means an unrealisable condition.

"It will be noticed that the period during which the currents are opposite, and during which repulsion can take place, is lengthened at the expense of the period during which the currents are in the right direction for attractive action. These differing periods are marked *r*, *a*, &c., or the period during which *repulsion* exists is from the zero of the primary or inducing current to the succeeding zero of the secondary or induced current; and the period during which *attraction* exists is from the zero of the induced current to the zero of inducing current. (It will be seen that the shaded portions in Diagram 23 have been widened out at the expense of the unshaded parts.)

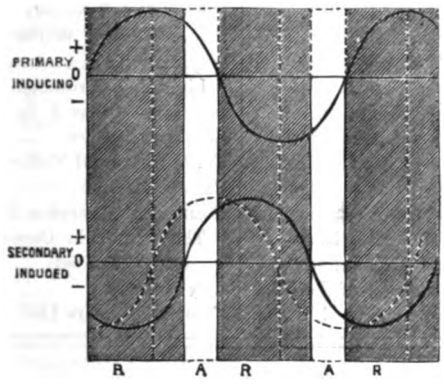

FIG. 23.

"But far more important still in giving prominence to the repulsive effect than this difference of effective period is the fact that during the period of repulsion both the inducing and induced currents have their greatest values, while during the period of attraction the currents are of small amounts comparatively. This condition may be otherwise expressed by saying that the period during which repulsion occurs includes all the maxima of current, while the period of attraction includes no maxima. There is then a *repulsion due to the summative effects of strong opposite currents* for a *lengthened period* against an *attraction* due to the summative effects of *weak currents* of the *same direction* during a *shortened period*, the resultant effect being a greatly *preponderating* repulsion.

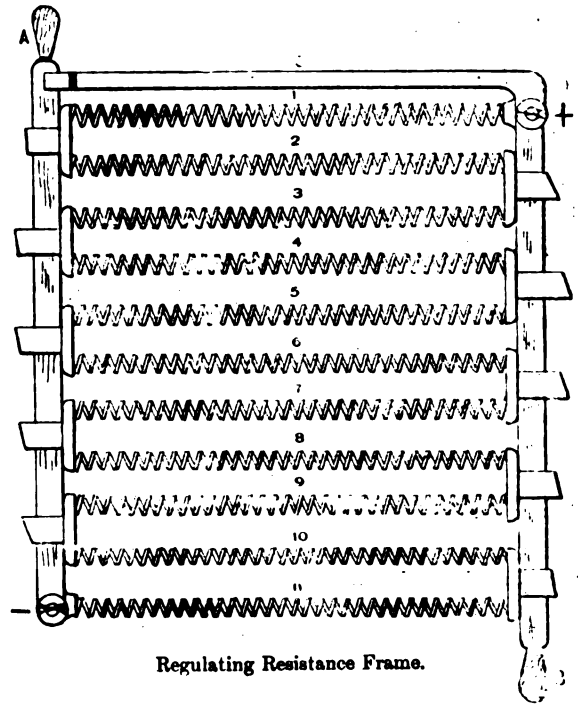
"It is now not difficult to understand all the actions before described as obtained with the varied relations of coils, magnetic fields and closed circuits. It will be easily understood, also, that an alternating-magnetic field is in all respects the same as an alternating-current coil in producing repulsion on the closed conductor, because the repulsions between the two conductors are the result of magnetic repulsions arising from opposing fields produced by the coils when the currents are of opposite directions in them."

(To be continued.)

A REGULATING RESISTANCE FRAME.

In an article on "Regulators," recently contributed to the *Electrical World*, Mr. Albert B. Herrick describes the following simple form of regulating resistance frame:—

When the lever A is in the position shown in the figure, the resistance coils are short-circuited from the positive pole through the metallic bar C, and then through lever, A, to the negative pole. When the lever A is withdrawn from contact with bar, C, all the resistance-coils are then in multiple arc between the positive and negative poles. In this position we have the maximum ampere-carrying capacity and the least resistance. The resistance is increased by still further withdrawing the bar A, when the coils 1 and 2 will be cut out and the resistance of the regulator increased. The resistance can be still further increased by steps until lever A, in succession, is withdrawn from all the contacts, when we will have only spiral No. 11 in circuit. The resistance may then be increased by withdrawing lever B, and the spirals placed in series. By this arrangement we have obtained a regulator having the maximum ampere capacity on the first step, with all the spirals in multiple, and a maximum resistance on the last step, with all spirals in series. If the resistance of spiral 11 is so proportioned that it will not take more current than the maximum when lever A is removed, all the rest of the regulator will have ample capacity. Such a combination only gives 12 possible steps, but a more complicated switch could be designed which would multiple series the spirals, and which would give us a greater number of combinations with these spirals, so that any desired number of steps could be produced between the maximum ampere capacity and maximum



Regulating Resistance Frame.

resistance. In any regulator energy must be wasted to produce certain variations in the current. From the point of economy they are abominable, but they are as necessary to the electrician as the valve is to the engineer.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, May 23rd.

CITY AND GUILDS OF LONDON INSTITUTE.
OLD STUDENTS' ASSOCIATION.

8 p.m. Smoking Concert at Anderton's Hotel, Fleet-street.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Manners and Customs of the Torres Straits Islanders." By Prof. A. C. HADDON, M.A.

SATURDAY, May 24th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Recent Excavations in Greece." By CHARLES WALDENSTEIN, Ph.D.

TUESDAY, May 27th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Natural History of Society." By ANDREW LANG.

INSTITUTE OF MARINE ENGINEERS.

7:30 p.m. Paper to be read: "Ventilation of Steamships." By D. G. HOEY.

THURSDAY, May 29th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Flame and Explosives." By Prof. DEWAR, M.A., F.R.S.

FRIDAY, May 30th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Astronomical Telescopes." By A. A. COMMON, F.R.S.

SATURDAY, MAY 31st.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Ballad Music of the West of England." By the Rev. S. BARING-GOULD, M.A.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and be crossed* "*Coutts and Co.*"

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

THE POLICY OF THE BOARD OF TRADE.

Some curiosity was evinced as to what Major CARDEW would have to say in his Paper announced to be read last week before the Institution of Electrical Engineers on "The Treatment, Regulation, and Control of Electric Lighting by the Legislature and the Board of Trade." The title was a comprehensive one, and manifestly gave scope for a wide discussion. It could hardly have been expected that he would be in a position to unfold new developments of Board of Trade policy, or disclose secrets hitherto locked up in pigeon-holes at Whitehall; and if any one had looked for such a thing the illusion must have been immediately dispelled by the author's opening remarks. Major CARDEW not only had no message to communicate, but he deprecated even a discussion of the past policy of the Board. In the face of this prohibition it was difficult to say what there was to be discussed; and the proceedings became almost devoid of interest. For the benefit of those who have never had the leisure or inclination to read through the two not very long Acts which deal with electric lighting, and the more tedious Model Forms of Provisional Orders, Major CARDEW gave a convenient summary of these documents, but no information which was otherwise beyond their reach. The subject uppermost in the minds of those present, and which the title of the Paper would obviously suggest to every one at the present time, was the transfer clause which the Board of Trade have inserted in the new Provisional Orders to be granted to Local Authorities. This, however, being most essentially a question of policy, was, under Major CARDEW'S conditions, excluded from the field of discussion. Since these columns are not fettered in the same way, we propose to offer some remarks on the subject, and to point out why we think the recent policy of the Board of Trade in respect of the Provisional Orders about to be presented to Parliament is open to very serious criticism, and demands at this moment the particular attention of all who are interested in the future of electric lighting.

There are certain well-defined limits to legislation by Provisional Order which appear to have been over-stepped by the Board of Trade in the present instance. A Provisional Order is a very convenient method of applying a general Act to a

Digitized by Google

particular case, but it is not applicable to original legislation. Where private rights have to be interfered with by the exercise of compulsory powers of taking lands, &c., or where authority is required to do anything which is not sanctioned by the general Act, the proceedings must be by a Bill in Parliament. No doubt, as a matter of mere machinery, a Provisional Order, when embodied in the confirming Act which is necessary to its validity, becomes a part of the law of the land. But Parliament is apt not to look very carefully into the contents of a Provisional Order which is brought up for confirmation. The Order comes before Parliament endorsed with a certificate, so to speak, of the Government Department which has granted it, that it contains all which the general Act requires, and nothing more than the law has already authorised to be inserted in an Order of the kind. The Electric Lighting Acts have undoubtedly left an unusual amount of details to be filled in at the discretion of the Board of Trade; but certain broad principles are laid down which the latitude granted in the treatment of details does not permit to be broken through; still less can matters foreign to the general principles of law be introduced. Now, it is a thoroughly-established principle of law that when Parliament has conferred special rights, coupled with corresponding obligations, these rights and obligations cannot be transferred by the statutory owner without the express sanction of the Legislature. A concession, which is hawked about and sold to the highest bidder, has hitherto been entirely unknown in this country, and the very name has a foreign sound about it. If we are now to see this kind of thing introduced in England, it is certainly an important development of our commercial policy, and a matter which one would hardly expect to meet with for the first time in a Provisional Order.

We noticed with some surprise a remark which the President of the Board of Trade is reported to have made in the course of the proceedings at a recent deputation: it was that the Board have the power to sanction transfers by Local Authorities. If these words are to be construed quite literally, probably no one would care to contest such a statement; but, if the President meant that his sanction would enable a Local Authority to transfer the obligations it has incurred under a Provisional Order, then the statement is certainly opposed to what, so far as we can ascertain, is the unanimous opinion of the lawyers who have considered the question. If, as we believe is unquestionably the case, the Electric Lighting Acts give no power to undertakers to transfer their liabilities, either with or without the consent of the Board of Trade, then it is an unconstitutional act to send up for confirmation by Parliament a Provisional Order which confers this power. The principle involved is, we think, of vital importance, particularly having regard to the terms of the clause as it appears in the Model Form of Order recently issued. No provision whatever is made for any one being heard in opposition to the transfer; and even if such a provision had been added, the safeguards afforded by an investigation before a Parliamentary Committee, where witnesses can be summoned and examined on oath, would still be wholly absent. The result of such an enactment, if it is allowed to be smuggled through Parliament in the unconstitutional guise of a clause in a Provisional Order, will, we believe, be most disastrous to the interests of electric lighting.

Local Authorities, who, in too many cases are notoriously interested in stifling electric lighting schemes, will hesitate no longer about getting the key of the situation into their own hands. The transfer clause will place the game in their hands; and they cannot be expected to decline so tempting an invitation to play at "heads I win, tails you lose." Having acquired a Provisional Order—or concession, as we shall have to call it in future—they will sit still as long as they can do so with safety, or until they can drive a lucrative bargain, and then transfer the whole undertaking on onerous terms, which will involve an early bankruptcy to the purchasers. It must not be supposed that this is an imaginary picture. An enormous impetus has been recently given to every branch of industry connected with electric lighting, which, when new schemes receive a check, will result in over-production. Manufacturers must find a market for their goods; and we cannot doubt that this will result in the fostering of unstable concerns, which will only too readily fall victims to the demands of Local Authorities.

Arguments are not wanting against Local Authorities being allowed to meddle at all in commercial transactions; but seeing that more than one-third of the total capital invested in gas-works is already under their control, it is too late to discuss this policy, which has, moreover, been expressly recognised by the Electric Lighting Acts. Parliament has declared that electric lighting shall be carried on under certain prescribed conditions, and that Local Authorities may, if they please, become undertakers in accordance with these conditions; but this is a wholly different thing to saying that they shall have concessions to traffic with, and that electric lighting shall thenceforward be carried on, not on the terms prescribed by Parliament, but on such terms as the Local Authority of each district may dictate. Such a system as this has never received any recognition whatever by Parliament, either in connection with electric lighting or anything else. It is absolutely a new principle, and the effect of it will be to stultify if not repeal a material portion of the Acts. Is such a result as this to be brought about by a mere confirmation of Provisional Orders? Is the hard-earned 42-years' term, which was granted by the Act of 1888, to be sacrificed without a struggle by the mere dictum of the Board of Trade, as a sop to influential Local Authorities? So important a change of the law, we maintain, ought not to be carried out without the fullest consideration of Parliament; and we think that the electrical trades will be wise to exert all their influence with members to secure that the Bill for confirming these Provisional Orders shall at least not pass unchallenged.

REVIEWS.

"Notes on Electric Lighting." By the Rev. GERALD MOLLOY, D.D., D. Sc. (Dublin: M. H. Gill and Son.)

These notes are a reprint of a series of articles which appeared last autumn in the columns of the *Freeman's Journal*. The first two chapters of the book are devoted to a general discussion of the various systems of electrical distribution, the principles underlying them, and the districts most suitable for their application. In Chapter III. we have a detailed description of the A.T. and B T. systems. In Chapter IV. the author "discusses the question of cost, and come to the conclusion that the evidence at present available goes to show that for domestic use the electric light can be supplied with profit at about 30 per cent. above the price of gas, for an equal amount of illumination; and that for street lighting, a public body working without profit can furnish a far more brilliant illumination than we now have at a price very little in excess of what we are now paying for gas. The last two chapters are respectively devoted to the Heisler and continuous-current transformer systems. This little volume may be read with advantage by anyone desirous of obtaining an elementary knowledge of the pros and cons of the many systems of electric lighting now competing for public favour."

ON LIGHTNING-GUARDS FOR TELEGRAPHIC PURPOSES, AND ON THE PROTECTION OF CABLES FROM LIGHTNING,

With Observations on the Effect of Conducting Enclosures.*

BY DR. OLIVER J. LODGE, F.R.S.

(Continued from page 40.)

I will now describe the principle of my own lightning-guard, and will then connect it to the circuit in place of Saunders', and show that it affords practically complete protection for both small and big flashes.

The principle is one very easy to understand. It is merely to take the overflow from one protector, and give it the chance of

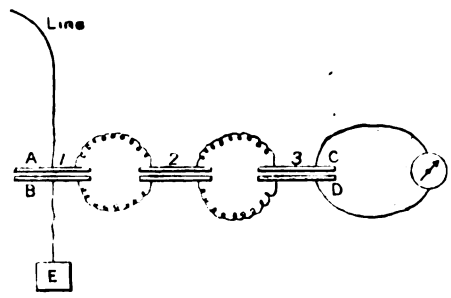

FIG. 8.

another, then to take the overflow from this and offer it another air-gap, and so on, till nothing is left; at the same time diminishing the overflow from each protector as much as possible by the use of self-induction coils, which impede the violently varying or alternating rushes by their electro-magnetic inertia.

Thus, for instance, using a series of plate protectors, we may couple them up as shown in Fig. 8.

Only a small fraction of a sudden shock will escape No. 1; say a thousandth part, since it is offered the inertia or impedance of the coils as the only alternative. A thousandth of this, again, may escape No. 2; and a thousandth of this, or a thousand-millionth of the whole, is all that is left for the galvanometer. By adding to the series, if it were necessary, it is manifest that a disturbance may be diluted down to any desired extent, with the rapidity of a geometrical progression.

I do not, indeed, propose to use plates commonly; simply because they are more bulky than necessary, not so easy to adjust, and not so open to inspection as knobs or points. Moreover, the first or exposed pair of such a series is likely to be damaged by lightning; and when damaged, it may be permanently short-circuited or otherwise inconveniently altered in a troublesome and invisible manner. I prefer that the terminals of the first air-gap hall be easy to examine, easy to remove, and cheap to replace.

The last air-gap of a series I prefer to be very finely adjustable, indeed, with screw adjustment; and all of them should be open to inspection, so as to avoid accidental contact on the one hand, or undue air space on the other. I therefore propose simple brass rods for the exposed air-gap, adjusted just far enough apart to exclude that disturbing thermo-electric or other effects caused by a spark occurring between their surfaces. All rods must be short, so that heat-expansion may not short-circuit them. The theoretically best place to tap off the useful current is from near the tips in contact, so as to tap off a minimum of impedance with a maximum, as thus, Fig. 9:—

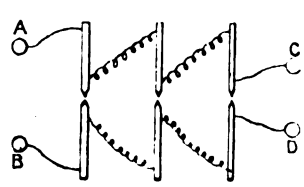

FIG. 9.—A, B, are the exposed, or line and earth, terminals; C, D, are the protected terminals. Corresponding terminals are lettered the same in all the diagrams.

Making a rough model of such an arrangement, with coils of a few yards of stout gutta-percha-covered wire, wound on cotton reels, I tested it by inserting a scrap of extremely fine wire between D and C, by holding them with wet fingers, and so on; but was unable to fuse the finest wire, or to feel any disturbance, although great flashes were going to A and B, and the early air-gaps were sparking properly. Large condensers, composed of great piles of window glass—the same condensers as I had used for obtaining very slow oscillation—and the discharge of which had a powerful deflagrating effect, were used in this experiment, as well as more moderate capacities, such as a Leyden jar battery and single jars; but still no effect at the protected terminals. This was the stage I had reached when I read my last Paper—the one on lightning conductors, &c., before this Institution.

I have now to report that Dr. Alex. Muirhead has kindly made me an actual and highly-finished instrument on this plan; designing it himself. This instrument I have here (Figs. 10 and 10A), and I have also received from him to-day this round and more compact and, I suppose, cheaper form of the same instrument (Figs. 11 and and 11A); with one-half the coils omitted, according to a plan of mine which, though not in all respects so theoretically satisfactory, may answer well enough for many purposes—as I shall mention further on.

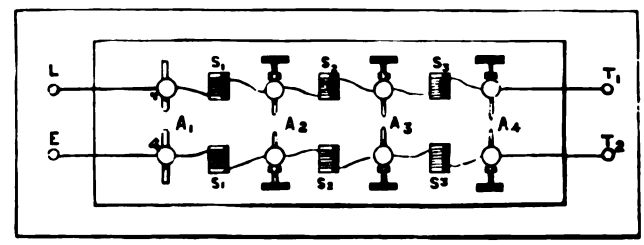

FIG. 10.

I now insert the first-mentioned protector in the path from Leyden jars to galvanometer, and I show that with all-sized flashes, from the smallest to the biggest here practicable, the galvanometer is protected; its needle does not move, neither does its safety valve sparkle. Examining it still more strictly and rigorously, I find that the insulation protection is indeed quite perfect; but a faint trace of a wave does pass round the galvanometer wire, and affects the needle slightly when in a sensitive condition. To see this clearly, one must allow the needle to recover from the disturbance due to the charging current before permitting the discharge. The galvanometer shows easily the charging current from a common frictional plate machine; in fact, the spot of light moves several inches with such a current. Connecting it up through the protector, with a small single-pair-of-plates inductive machine charging the jars and giving pretty long sparks, the usual occurrences observed are as follows:—Between each spark, while the jars are charging, the spot of light deflects considerably, gradually less as the jars get fuller, until they discharge; when, instead of a kick back, as one might expect, there is rather a leap forward, by reason of the suddenly restored strength of the now almost unopposed charging current.

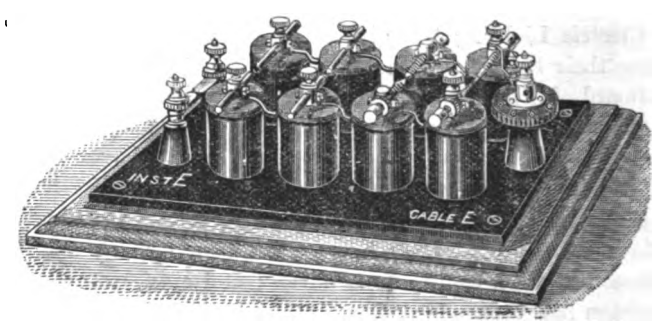

FIG. 10A.

Whenever we thus want to see the charging current, we must of course make fair metallic contact with the outsides of the jars, so as to close the circuit through the galvanometer; but, in order to further test the instrument, I make a break at one or both of its terminals, and allow flashes to strike either L or E, or both. It is not really a more severe test than the other—not quite so severe, in fact; but it looks worse, perhaps, and at any rate it is the simplest plan of keeping the charging current out of the galvanometer, and so securing that the needle shall be ready to indicate the slightest effect which the unfiltered off portion of the discharge is able to produce. But there is practically no effect to be seen.

* Paper read before the Institution of Electrical Engineers, on April 24, 1890.

Digitized by Google

You observe that my instrument is symmetrical, *i.e.*, that there are just the same coils in its earth-connected as in its insulated portion. It may easily be supposed that this doubling of the parts is unnecessary, or even deleterious. It may be plausibly argued that coils interposed in the earth connection are bad as well as useless, and that both the terminals on that side, E and T_2 should be agglomerated together; that, in fact, a preferable pattern would be that shown in Fig. 11, where there is only one earth terminal towards which all the others point. I think, indeed, that there are many cases where this will serve sufficiently

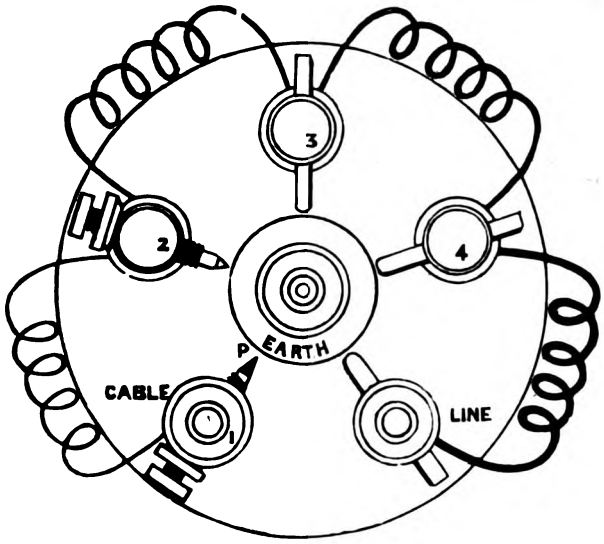

Fig. 11.

well, but I do not regard it as so theoretically sound as the other, for this reason. It proceeds on the assumption that every disturbance arrives from above and is anxious to make its way to the earth. But we have no guarantee that such shall be always the case; disturbances are as likely to reach the apparatus from below, surging up from earth to line, and in that case the coils are wanted in the earthed half of the instrument. I return to this question later.

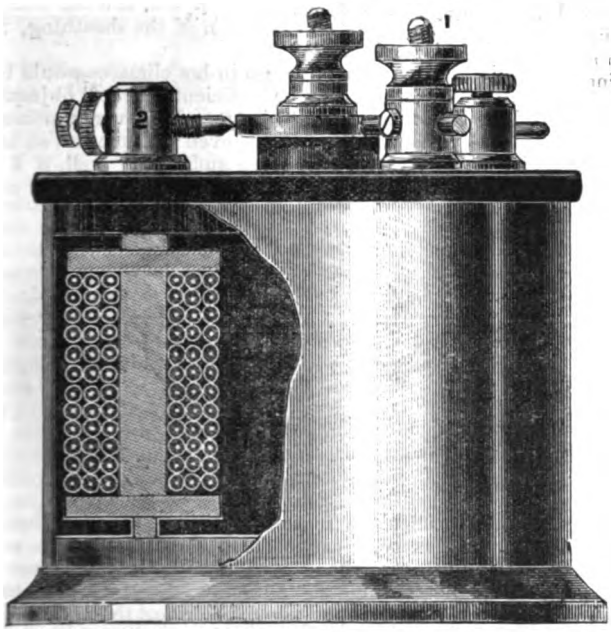

Fig. 11a.

When I speak of a disturbance travelling from earth to sky, instead of from sky to earth, I do not mean that in one case the sky is negative and in the other positive; questions about sign of charge having nothing to do with it. There is some amount of unnecessary haze abroad on this matter. Think of a sudden electrical disturbance imparted to a thin isolated copper wire; it starts at some point and flashes along the wire with precisely the speed of light, and the electric wave or pulse reaches the different portions of the wire in successive epochs of time.

Instead of a single wire, think of what must always exist, viz., a closed circuit; two pulses or waves originating at some point of this circuit flash round it both ways, at a pace usually rather less but never more than the speed of light, and meet at the antipodes of the starting point. If the circuit is unclosed, each pulse will get reflected and return, surging to and fro perhaps several times, and in such cases any point of the wire is reached by pulses travelling first one way and then the other—a phenomenon very characteristic of disruptive disturbances; but the first pulse is likely to be the strongest. It must be clear, I think, that for such alternating currents, as well as for rushes of uncertain direction, a symmetrical protector is best.

To illustrate these things, make a few more experiments with Saunders' protector, which I choose as one of the best; any other will do.

Experiment No. 8.—Connect a Saunders' protector to earth and to any line wire in the proper way, and attach a single wire to the "protected" terminal: like the wire CG. in Fig. 3. Now send a discharge between line and earth either way, and the "protected" wire will be found ready to give off sparks at every flash. It will spark to anything: to the earth, to an insulated body, even to its own earth screw B or D. Connect to it a galvanometer, or, better, a coil of wire one has no compunction in spoiling; then if the far end of the coil be attached to anything, either to the earth or to another line, or to an insulated body—even an insulated body of small size—sparks between the turns of wire will demonstrate the fact that the insulation is being broken down by the lateral waves rushing along the nominally "protected" wire, and being either reflected or absorbed according as it is connected to an insulated body or to the earth. The connection which permits least disturbance is to the screw B or D. But there must be no chance of the galvanometer being either purposely or accidentally connected to earth in some other way also, else even this partial protection has its virtue removed.

Experiment No. 9.—The "earth" in the previous experiment being the gas pipes: instead of striking the instrument by a flash direct, let a flash be imparted to the gas main at some other point—say, in another room—to typify the possibility of a lightning flash striking the earth in the neighbourhood of a telegraph station. Immediately some of the charge splashes up from the earth, and the protected wire again emits a spark; or, if it be connected to anything by a scrap of fine wire, that wire may be deflagrated. Thus we see that earth connection is not so utterly safe as might be supposed: secondary surgings may rise up out of the ground and do damage to whatever is conected to it. I believe there are more instances of such occurrences than are usually recognised. But I prefer to leave the enumeration and discrimination of instances to persons of experience.

Experiment No. 10.—But now insert in the so-called protected wire an arrangement of air-gaps and self-induction coils, after the fashion which constitutes my system of protection (Fig. 12). Then,

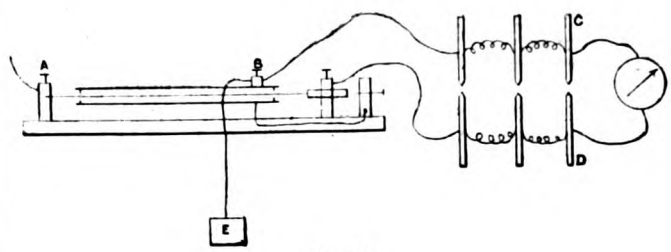

Fig. 12.

inserting a fine wire, or a coil, or a galvanometer, or any other detector, in the interval, and connecting the far end of the wire to anything as before, it will be found that although every trace of signalling current is able to affect the galvanometer, no appreciable trace of a violent disturbance is felt there; it is now securely protected whichever way the disturbance comes.

The electro-magnetic inertia possessed by the coils protects it from sudden currents in the same manner as the inertia of a penny protects it from disturbance when it is balanced on a finger with a card under it, and the card smartly flipped away. It is not, however, to be supposed that inertia alone, without successive air-gaps, can exert this protective influence. The coil of a galvanometer has plenty of the required impedance, far more than the thick wire coils on my instrument, but the only effect of that is to shunt violent disturbances through the insulation—by no means a satisfactory property. The *combination* of air-gaps or escape valves along with obstructive inertia is essential to the device. Let me here interpolate the remark that the self-induction of my coils is quite small; a very small amount of wire thus distributed suffices. Three or four yards of No. 16 wire are all I need use. I am well

Digitized by Google

aware of the objection to introducing great self-induction in circuits where rapidity of signalling is desired.

With respect to the use of the one-sided pattern (Fig. 11), its effect will be represented in Fig. 10 if the right-hand set of coils are short-circuited out by a thick wire. In that case the galvanometer, though it is protected from disturbances arriving from the left, is exposed to those coming from the right.

This dichotomised pattern is therefore only permissible when there is a fair presumption, or complete certainty, against disturbances arriving this way. Cases of this sort will be mentioned in connection with the protection of cables.

The patterns so far drawn correspond rather to the sort suitable for a terminal station; but for an intermediate station where an "up" and "down" line wire meet, but where there is no necessary "earth," except an earth adapted to filter off lightning disturbances from the wire instead of passing them from station to

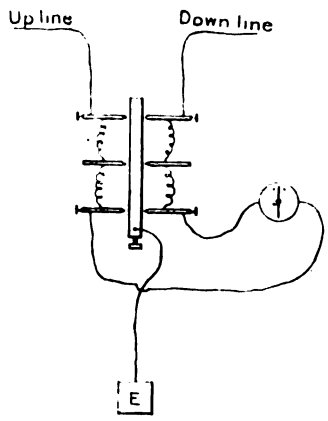

Fig. 13

station, the above pattern is suitable (Fig. 13). It explains itself; it is virtually the round pattern doubled.

Submarine Cables.

All that has been said applies by implication to the protection of cables, as much as to any other sort of covered wire out of which it is desired to keep violent rushes of potential, but about cables there are a few special things to be said which we will proceed to say now. Not only is a cable a tremendously valuable piece of property in which a slight fault costs a large sum to repair, and hence the utmost precaution ought to be taken in their case (even the instruments employed in signalling being so expensive as to deserve a thorough protection if it can be given), but the fact that cables are always coated with a stout metallic sheathing is a peculiar circumstance not found in the lines of land telegraphs, whether overhead or underground, and it is a circumstance which, I wish to point out, renders their complete protection from lightning peculiarly definite and easy.

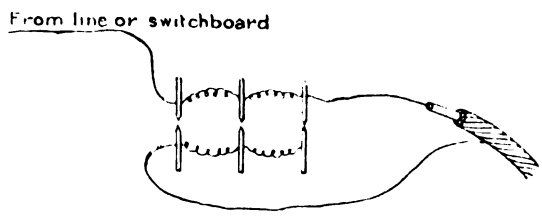

Fig. 14.

First, it is clear that risk is run wherever a cable is connected to a land line. I do not suppose this is ever done with the long ocean cables; but for short lengths, across gulfs, &c., I suppose transmission is usually immediate. Even with ocean cables I understand that the land line to the station is often led to the same switch-board as the cable instruments are connected to; and whenever there is any sort of proximity of this kind, a flash received by some distant part of the land line must be liable to spit across some of the terminals and flick off a bit of itself into the cable and its instruments.

Two lightning switches at least ought to be employed in every such station: one, a coarse one, at the place where the land line enters the building, to eliminate the grosser violence; and another, a fine one, at the mouth of the cable, to filter out the last traces of dangerous disturbance.

A proper mode of connecting one of my protectors to a cable is shown in Fig. 14. Here the outside sheath of the cable is used as sole earth, as is, I believe, customary. Another proper mode is to have a subsidiary or local earth, connection being made as in Fig. 15.

I am not prepared to support one of these in strong preference to the other. The second plan, however, is not to be adopted without the local earth. If there be no local earth, the first is the only proper plan, for it permits disturbances coming down the line to get to the outer sheath of the cable as directly as possible, the interior being protected by impedance; it also permits disturbances surging up the cable sheath, as they may when the shallow shore water is struck by a flash, to get to the line capacity directly, and not to easily enter the cable core.

But now suppose a case where no land line or connection is permitted to come within many yards of the cable station, though I suppose such a plan would be extremely inconvenient; let the cable be connected to nothing but its own instruments—where is the need of a lightning switch then?

The only danger that can occur now is when these instruments are struck direct, either from the roof or walls, or from gas pipes, or from the earth upon which they stand. A filter must therefore be arranged to protect the cable, even in this case. No fragment of cable core exposed outside its sheath can be considered safe. It would only be quite safe if it could be wholly put inside its metallic sheath and kept there.

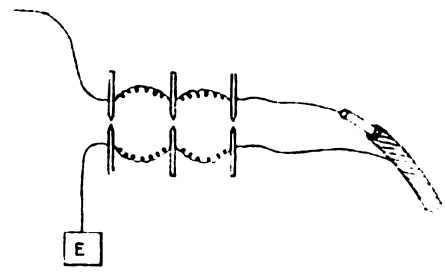

Fig. 15.

But while so carefully contemplating the protection of the cable, why not protect its instruments as well?—for a siphon recorder and an artificial cable are no cheap toys. It can be done perfectly well. Put them all inside the sheath of the cable, and they are safe. Of course the sheath of the cable must be enlarged to receive them, but that is easy enough. Use a metal house, and at the point where the cable enters it attach thoroughly its sheathing wires to the house, making a good joint all round, and the thing is done. The cable station is now an expansion of the sheathing, and everything inside it is perfectly safe.

It may be objected that a metal house in hot climates would be a nuisance. Very likely; there may be sufficient practical objections to the plan, but that is for others to judge. However, continuous sheet metal is unnecessary. Wire gauze, even with meshes so large as is used for poultry yards, may serve sufficiently well, if a few stout wires be added to make effective contact with the cable sheathing.

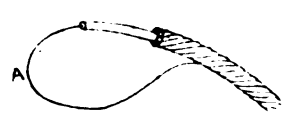

Fig. 16.

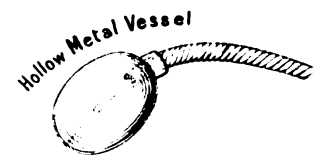

Fig. 17.

Unless practical difficulties in so casing in a cable station are greater than any I foresee, I cannot help thinking that it would be worth while, because then, even during a thunderstorm, the operators might continue signalling in undisturbed security, instead of having to suspend operations, disconnect the instruments, and short-circuit the cable to its sheath. Slow trails of disturbing current might indeed render signalling difficult or even impossible, but there would be no danger.

Reliance is commonly placed on the short-circuit of cable and sheath. If the short-circuit is very short indeed, the reliance is fairly justified; but if it be effected by a loop of any size (Fig. 16) then there is no absolute security; for a flash striking at A will bifurcate, and part of it rush into the cable. It may be said that that will not matter, because another part of it will be travelling down the outside, and that hence the G.P. between the two pulses (the internal and the external) will not be strained. But there is no guarantee that they will travel at the same rate.

Digitized by Google

There is indeed every certainty that they will not. The outside pulse, moreover, will soon dissipate itself by leakage into sea water, leaving the internal one to work its way out through any weak place it can find. Several hundred volts is a very insignificant potential for such a pulse, but it is not customary to apply several hundred volts to a cable with equanimity.

But if instead of a mere loop we put a thimble or hollow metal vessel over the end of the cable, connecting its sheathing to the walls, and connecting its core to the interior, then no sudden splashes can enter the cable at all, they will keep to the outside and do no harm (Fig. 17).

Such a magnified thimble is the proposed metallic or wire-netted cable station; and it is one that has the advantage of never needing to be removed; one which contains instruments and operators, and protects them all alike from dangerous disturbances (Fig. 18).

It may be asked whether such a house should depend for its earth entirely on the cable sheathing, or whether a local earth should be provided.

It is not a vital point, but a local earth is to be recommended in order that even the outer sheath of the cable shall not have to carry flashes of exceptional violence, which might unduly heat it. Extra earthing the house can do no harm, and may thus occasionally do good. But do not think of sending out to any local earth a wire from the earth terminal of the recorder or any testing instrument inside. The inside of the metal house is their appropriate earth, and no other must be permitted. Again, gas pipes, water pipes, and everything else may be permitted to enter the house, but only on the strict condition that they be effectively united to it at their point of entering—not at some other point. Connecting them or anything else to the house by a mere wire is not a bit of good. The cable, the gas pipes, and every other

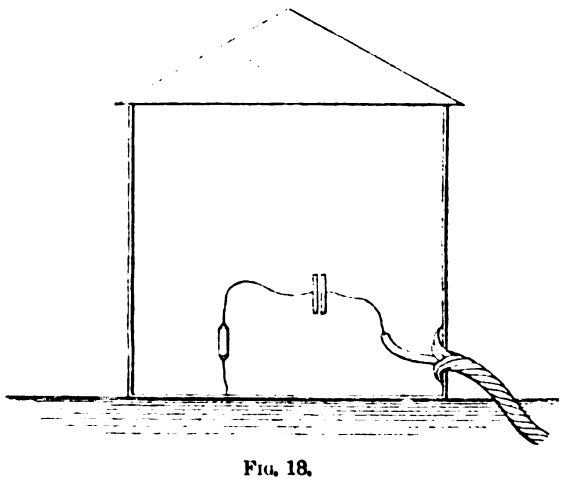

Fig. 18.

conductor which penetrate the walls of the house must be *at that place* united to those walls. I have ample experimental as well as theoretical grounds for this assertion. No insulated conductor must be allowed to protrude, unless it be enclosed in a metallic sheath connected to the walls, with the distant end of this sheath itself closed. Such an insulated conductor is, of course, the core of the cable itself; the completing closed sheathing being the distant cable station. If that be a mere wooden shanty disturbances may there enter the cable, and not only do it damage but derange the signalling power of your instruments at this end also; all your fine protection being no good if not imitated at the far end of the cable.

Since no insulated conductor must on this plan be allowed to penetrate the walls, it is manifest that no land line can be permitted to enter a cable station. The land signalling station must be a separate chamber. It need not be a distinct building; it may be under the same roof, but it must be wire-fenced off from the cable compartment, and the messages must be put through non-electrically.

Whether such a separation is too inconvenient to be contemplated I leave to those with more practical knowledge to say. I am only pointing out what is necessary for absolute protection. Of course, a reasonable amount of protection can be obtained under less stringent conditions, and I am by no means laying down the law as to what ought to be done in practice; all I say is, that unless all this is done the protection will not be absolute. Practical men are far the best judges of questions relating to temporising and expediency. For instance, windows and doors are necessary in a cable station, and although they may be fenced over with wire netting, it is not to be supposed that in all conditions of practice they will never be left open, or that there will never be a break or a serious imperfection in the continuity of the metallic sheathing to the house; and in face of the liability to such accidents, it is not to be supposed that proper lightning-guards can be dispensed with. They will, however, then become the last citadel of security, and not, as at present, the outer line of defence.

It is customary, I believe, to land the ends of cables in a cable hut on the beach, so as to be able to get testing instruments as close as possible to the real thing, undisturbed by insignificant shore leads. There is not the slightest difficulty or danger introduced by this practice, provided the hut or an enclosure inside it is made of iron, and both cable and shore lead are well connected to its walls by their outer sheathing as they enter it. Testing instruments and all inside the enclosure are then perfectly safe, except from disturbances conducted in through the central core of the lead; and this can only happen when there is some great defect at the cable station. It is this lead from hut to station which now represents the cable, and all the care described as proper to be taken of the cable must of course be taken of it.

The cable hut need not be itself of iron; if it contains an iron box, as shown in Fig. 19, all requirements will be satisfied, and such a plan may perhaps be convenient; the lid can be removed for occasional testing without appreciable risk. In case a trace of disturbance should by chance get into the lead, a lightning switch may, for a final appeal, be included in the box.

I said above that there were cases when the dichotomised pattern of Fig. 11 was sufficient. This is one of them. There is not the slightest objection to a single terminal here, connected with the inside of the box, because nothing violent can splash up into it.

The box may advantageously have some rude local earth of its own, merely in case its hut should happen to receive a direct flash of lightning.

Experiment No. 11.—To demonstrate the protecting action of cages I put a parrot cage over a thin wire reflecting galvanometer standing on a copper plate through which a lead-sheathed cable passes, the lead being attached to the copper where it passes through the hole by a number of soldered wires. If this junction is defective the experiment is liable to fail—*i.e.*, the protection will not be thorough. The cage also should be well connected with the copper plate. The terminals of the galvanometer are connected,

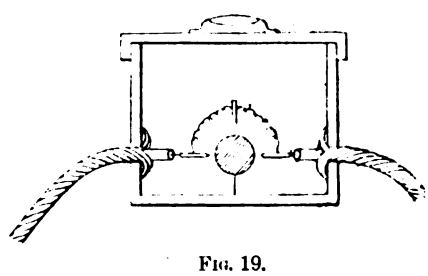

Fig. 19.

one to the inside of the cage at any point whatever, the other to the core of the cable. The distant end of the cable may be similarly treated, or for simplicity its core may be directly connected to its sheathing, and a tight-fitting metal thimble or hat put over it. Before doing this, however, I apply something representing a signalling E.M.F. to the distant end, to show the sensitiveness of the caged galvanometer—*e.g.*, touching the core and its sheath simultaneously with a pair of wet fingers immediately drives the spot of light off the scale.

All being properly arranged, flashes are sent from a jar to any point of the cable—to its far end, or to the cage of the galvanometer, &c.; some other point of the cable or cage being earthed. Not a wink does the needle show, at any rate to cursory inspection; and if a safety valve be supplied, no matter with how microscopic a spark gap, it cannot be made to overflow.

But, all the time these flashes are going on, an operator in the distant cage may be sending voltaic currents along the cable and signalling to the sensitive galvanometer inside the cage without any disturbance from the violent rushes outside.

It is not to be supposed that such cable houses afford any protection against earth currents, or any other steady or slowly varying effects. These will produce their full effect quite careless of the fact of metallic enclosure. Nothing but a *perfectly* conducting screen can entirely protect against them, and that is not a likely invention. Atmospheric disturbances also, and even discharges, *in so far as they are slow* or leave subsiding effects behind them, will be felt by the galvanometer; but then, although inconvenient to a reader of signals, slow disturbances are not dangerous. It is the violent and sudden rushes that are dangerous, and these are wholly excluded, occurring only in the outer metallic sheath. To exclude steady currents of too great strength a short length of very fine wire must be included in the circuit.

Digitized by Google

Experiment No. 13.—To emphasise the fact that the galvanometer is not in the smallest degree protected from steady currents, except in so far as the resistance of core and bobbin bears a large ratio to the resistance of sheath and cage, according to rudimentary laws of divided circuits, I take the terminals of a single storage cell and touch them to two points of the outer sheath of the cable an inch apart like A B (Fig. 20). Instantly the spot of light is flung off the scale. Apply the terminals to points one-eighth of an inch apart only, the needle is still strongly disturbed; and, indeed, it is only by very careful feeling about and adjusting within the hundredth of an inch on the same sectional circumference of the cell-sheath that a neutral position for the second terminal can be found, and the galvanometer ceases to tap off any fraction of the current. Diagrammatically the arrangement is this:—

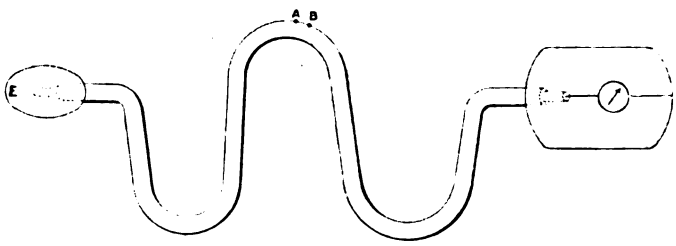

Fig. 20.

With the terminals at A B the galvanometer plainly receives a minute branch current, unless A B are coincident.

The simplest way to realise the matter is to recoganise that when a current is passing in the sheath from A to B all the left-hand portion of the cable is at A potential, and all the right-hand portion is at B potential; hence, of course, there is a tendency to leak along any available path between the two portions; and the core is such a path.

But Leyden-jar flashes may be sent, not merely to points close together like A and B, but to points as far apart as you please, like E and F, and the galvanometer shall show nothing.

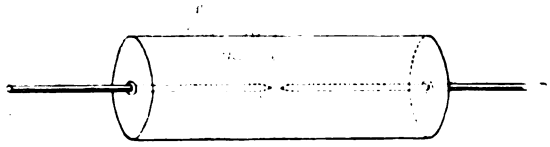

Fig. 21.

But now arises a very interesting question. The protection thus illustrated, is it theoretically perfect, or only perfect enough for all practical purposes? Does a metal cage protect a galvanometer absolutely from these sudden disturbances?

Put it in another way. Everybody knows Faraday's cage, or metal-lined room, into which he went with electroscopes, birds, frogs, and other instruments, arranged that the outside should receive violent flashes, and detected nothing inside. Suppose he had added to his stock a galvanometer, connecting its terminals to two points of the walls, would he have got anything then? It naturally occurs to ask, why did he not try it? What would he have expected the result to be? Did he perhaps not try it because he felt already sure of the result? If so, the feeling of certainty was premature. Whether his guess might happen to turn out right or no, he certainly had not all the facts before him on which to base an opinion.

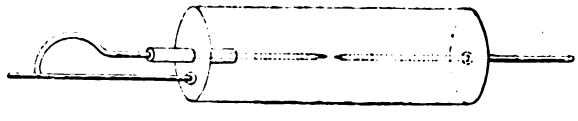

Fig. 22.

Let us go into the question. First of all, Mr. Chattock and I obtained the following result a year or two ago, viz.: that between two wires wholly inside a wire-gauze house not a trace of spark can be obtained, whatever flashes pass along the outside. The only way we got sparks inside a metal enclosure was by allowing one of the wires to protrude a little through a hole in the walls without touching the sides of the hole.

Thus, for instance, Fig. 21 gives no sparks inside, but Fig. 22 may give some very small ones.

But this last is hardly a fair device; it is equivalent to turning a portion of the enclosure inside out; the protruding wire should be a part of the interior surface. Inside a thorough and fair metal enclosure sparks cannot be got between its walls.

Recently Hertz tried what is practically the same experiment, his object being to demonstrate that rapidly varying currents traverse only the outside of a conductor (*Phil. Mag.*, August, 1889). He took a sort of mouse mill of wires (Fig. 23), and, inserting it in a place where sparks would naturally occur between the axial wires, he found it not possible to obtain any until many ribs of the mouse mill had been removed so as to leave a great gap for the penetration of electro-magnetic waves, or unless he coated the glass tube portion of his enclosure with only a film of silver so thin as to become incipiently transparent to such waves—*i.e.*, transparent to light. All this shows clearly why a cage protects a cable; no sparks are possible inside, and therefore its insulation cannot get damaged.

But what about a galvanometer or telegraph instrument?—*i.e.*, what about the conduction test? Insulation is safe enough, but will the signalling be interfered with during the continuance of a storm?

Well, if we try the experiment by putting a galvanometer inside a good conducting vessel and attaching its terminals to the walls—a small patch of gauze being, of course, provided for the ray of light to get in and out—nothing will be seen when ordinary flashes are given to the cage; and that must certainly have been the result of the experiment if it had been tried in Faraday's time with the galvanometers of that day.

But a galvanometer is in this arrangement so severely handicapped by short-circuiting that it is perhaps unfair. So modify it by using an elongated form of enclosure and attaching a low-resistance galvanometer to points of it a good distance apart. The metallic sheathing of a cable is such an elongated enclosure; hence modify the simple cage experiment thus:—

Experiment No. 14.—Instead of the thin-wire galvanometer, which we find easy to protect, encage a thick-wire galvanometer and join it up to the lead-covered cable as already described, with good connection between cage and sheath. Sheathe also the distant end, and connect up as in Fig. 20. Now send flashes to E or to F, or to both; or spark to E, and let F be earthed, or *vice versâ*. The galvanometer gives a slight kick at every flash. Its safety valve shows nothing, but a feeble pulse does pass round its wire.

Fig. 23.

When I first got this effect the cage employed was a common parrot cage; but, since its wire junctions could not be depended on, I had one made of fine copper gauze, soldered to a disc of copper at top and to a flat ring at bottom, suitable for clamping down to a copper plate. The same disturbance being still found when it was used, a solid sheet-copper water-tight hat was next made and soldered down to the plate, the gauze cage being placed over it as a supplemental and outer covering. Still the residual effect remained, apparently unaltered in strength.

The protection of a galvanometer from these sudden discharges is, therefore, not theoretically complete. No amount of covering-in can absolutely eliminate all disturbance. No matter how sudden a pulse may be, so long as there is an integral passage of electricity in one direction along a conductor, the central portions of that conductor will convey some trace of it. The integral passage of electricity along the axial wire is, in fact, that determined simply by its relative conductivity as compared with its surrounding sheath, irrespective of more complicated considerations. But whereas in the outermost layer of the sheath there are violent surgings, the current-strength being very great and alternating, nothing of the sort occurs in the central portions; the violence is all damped out, and there remains nothing there but a quiet and sluggish flow. The rush in the outer layer of a conductor induces currents in the layer next below, these again in the layer below that, and so on; a sort of diffusion of currents occurring towards the axis, like the diffusion of heat in a body to whose surface heat, or an alternation of heat and cold, has been suddenly applied. Such diffusion is accompanied by a flattening out of the waves, a decay of all their suddenness, so that the axial disturbance is a mere peaceful flow, analogous to that given by a voltaic cell, not having a trace of jump left in it. The very smallest breach of continuity stops it altogether: it is impossible to get a spark in the axial wire; but if this wire be a completed conductor it takes its share of integral current along with the rest. Not simultaneously, however; this diffusion inwards occupies time, but the delay has no particular effect to call for notice here.

Another way of putting the matter is to use the mechanical analogue of slipping wheel-work as representative of a conductor;

Digitized by Google

then, if the outer layer of wheels be spun to and fro violently and left with a certain residual spin, to represent the impact of electro-magnetic waves from the dielectric on the metal, that residual spin will penetrate to all parts of the geared mechanism, except where there is absolutely perfect slip—*i.e.*, except into space bounded by a perfect conductor.

To suppose that the axial part of a conductor (whether solid all through or hollow with a wire along its centre makes no difference in principle) takes no part in conveying a momentary transfer of electricity, is to make the same error as is published so uniquely and interestingly by Sir William Thomson in the March, 1890, *Phil. Mag.*, wherein he corrects his original idea that the ordinary resistance of a ballistic galvanometer wire would not be the right resistance to introduce into its formula, because the outer layer of the wire conducts most of the current; and shows that, examining the matter still more completely, every part of the wire is ultimately effective, and equally effective as regards integral flow. All the rush does go by the outside at first, and all the *violence* is there expended anyhow, but every part of the section does its full share of conduction ultimately.

It is worth entering thus fully into the matter, because these are things about which it is easy to get bothered if one does not happen to get hold of them right way up. And this matter of protection by cages is one on which there has long been some uncertainty or hesitation.

Now that I see clearly how they act, their behaviour seems natural enough, and what one ought to have expected—what I think Maxwell (doubtless others also) would have expected; certainly it all comes out clearly enough on his principles. But a little time ago the matter was by no means so clear in my mind, and I rather gather that several others felt a similar sort of temporary uncertainty.

One more way of putting the result may be permitted. It is not given as an experiment, because I have not tried it. Take a sheet of metal or gauze, tap it along a certain line with a galvanometer on one side and with a spark gap on the other, arrange to send flashes along the same line, and then fold the sheet into a cylinder either upward or downward, so as to enclose at pleasure the galvanometer or the spark gap, but not both (see Fig. 24).

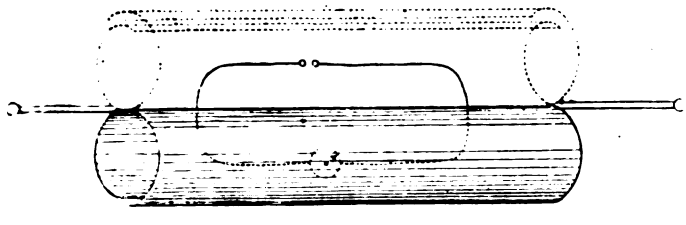

Fig. 24.

The indications of the galvanometer will be wholly unaffected by the way the sheet is folded, or whether it be left flat, provided always the insulation of its wire is and remains perfect. But to the air gap the folding of the sheet makes all the difference; when enclosed it will be quiescent, when exposed it may sparkle.

DATA AND PLOTS OF VARIOUS INCANDESCENT LAMPS, TOGETHER WITH AN IMPROVED METHOD OF TESTING.*

BY W. L. PUFFER.

Since the appearance of the report of the Franklin Institute on incandescent lamps in 1885 there have been no published measurements either of the efficiency or of the distribution of light of the best-known lamps now in the market. The Franklin Institute data, therefore, although very valuable as showing the state of the art in 1885, are of no especial value for use with the lamps now manufactured. The following data and curves have been calculated and plotted from the observations made by Messrs. Walter G. Whitmore and Edwin R. Pearson, class of 1887, Massachusetts Institute of Technology, who took as the subject of their graduating thesis "A Study of the Efficiency of Incandescent Lamps." The method used is substantially like that of the Franklin Institute, but I have changed and improved the method of plotting so that the five plots tell the distribution of light, shape of filament, and its position in regard to photometer, &c. This method of testing lamps is in regular use in the laboratory, with very satisfactory results.

* Abstracted from the *Electrical Engineer*, of New York.

The standard of light used is a Methven screen, which has been standardised by comparison with many standard candles at different times and by different observers, and also with a Harcourt standard burner. The photometer is a modified Bunsen, 100in. long, graduated into inches and tenths by a dividing engine, and having also a scale of "ratio" which, when multiplied by the candle-power of the standard, give candle-powers directly. Both the standard burner and the lamp under test are thoroughly screened, so that little if any diffused light reaches the eye of the observer. A key near the observer's hand and a lamp overhead furnish light when needed for reading.

The lamp-holder is quite different from that used by the Franklin Institute, and will hold any of the lamps now in the market without danger of straining. The socket, with lamp under test, is screwed on the end of a brass rod, which is free to slide or rotate in a sleeve fixed in the centre of and perpendicular to a disc of brass. Set screws are provided for clamping the rod in the sleeve. The disc is arranged on the bottom of a U-shaped strap in such a position that it can be turned, while the rod always remains parallel to the sides of the U and in the same plane. The disc has notches every five degrees, and the strap carries a locking pawl, which also serves as an index. The U-shaped strap is pivoted near the top in a frame, so as to have rotation about a horizontal axis; it also has a notched disc, and the frame a pawl and index. One arm of the U is longer than the other, and carries a movable counterweight. This apparatus is set with the horizontal axis perpendicular to the line of the photometer and on a level with the centre of the greased disc, the vertical circle being adjusted to read 0deg. when the lamp stands vertical with the socket underneath; then the horizontal disc is placed at 0deg., and the rod carrying the lamp moved till the plane of the shanks is perpendicular to the line of the photometer and the horizontal axis cuts the filament midway of its length. This position of the lamp is called the "standard position," and the photometer reading for this position the "standard reading." By means of the horizontal circle any desired degree of longitude can be instantly turned towards the photometer, and, by the vertical circle, any degree of latitude.

Electrical measurements were made by a set of carefully calibrated Thomson's current and potential galvanometers, placed in a room free from magnetic disturbances, where the value of the earth's component had been determined. As the current taken by the potential galvanometer bears a very sensible ratio to that in the lamp, the instrument is always kept in circuit, and a correction is made for the current passing through it. An adjustable resistance in the lamp circuit enabled the observer to keep the potential at the right amount. The potential galvanometer used was adjusted for Rayleigh volts.

When the lamp had been placed in the "standard position" and the potential adjusted, candle-power readings were taken at 65 different positions; the value used for each position being the mean of three or four settings of the disc, according to the method used by the observer. The standard direction, to which all others are referred, is a line perpendicular to the plane of the shanks of the filament, and lying in the equator of the lamp. By equator is understood the line cut upon the glass globe of the lamp, when upright, by a horizontal plane half-way up the filament. Zero point, or 0deg., is the starting point for measuring the angular rotation of the lamp, and is at the intersection of the standard direction and the equator.

Horizontal distribution is measured by candle-power readings at each 30deg. around the equator, beginning and ending with 0deg., or the "standard direction." Of these 13 candle-power readings, the first and last should, of course, check.

Mean horizontal candle-power is the mean of the first 12 of these readings, the check reading being omitted.

Vertical distribution is measured on each of four complete meridians, *i.e.*, those of 0deg., 45deg., 90deg., and 135deg. on the equator. On each of these four circles candle-power readings are taken at every 30deg. (of latitude), beginning and ending with 0deg., thus giving 13 readings, the first and last of which should check.

Standard reading is the mean of all readings in the direction of the zero point ("standard position"). It is an arbitrary position selected for convenience. By it and the "reduction factors" the candle-power (spherical or horizontal) may be determined under any given potential or current, at any subsequent time, by one reading. Great care should be taken in placing a lamp in this position, because in some lamps a very slight error would make a very considerable difference in the candle-power, and, of course, in the "factors." When a number of tests are to be made on any one type of lamp, it is preferable to select a point on the horizontal circle in that part of the curve where the rate of change of candle-power is very small, and so avoid error due to hasty or imperfect setting of the lamp for the standard reading.

Mean spherical candle-power is computed from 38 readings, selected from those described, with the aim of obtaining the average

intensity of light in all directions. These readings are as follows:—

Mean of 4 north pole readings (longitude 0°, 45°, 90°, 135°) counts							1
Longitude	0°,	Latitude	60°,	120°,	240°,	300°,	giving 4
„	90°,	„	60°,	120°,	240°,	300°,	„ 4
„	0°,	„	30°,	150°,	210°,	330°,	„ 4
„	45°,	„	30°,	150°,	210°,	330°,	„ 4
„	90°,	„	30°,	150°,	210°,	330°,	„ 4
„	135°,	„	30°,	150°,	210°,	330°,	„ 4
Equator, 12 readings (or mean horizontal × 12) counts							12
South pole reading assumed zero and counts							1
Total							38

The values for these positions are selected, added, and divided by 38.

Horizontal reduction factor is the mean horizontal candle-power divided by the standard reading.

Spherical reduction factor is the mean spherical candle-power divided by the standard reading.

The mean spherical candle-power divided by the mean horizontal candle-power gives a very useful factor, which is not so much affected as the two above by a slight error in setting the lamp in the exact standard position. Obviously the product of the standard reading taken at any time and the reduction factors will give the horizontal or spherical candle-power without any other measurements.

The method of plotting the results of a test on a lamp is thought to be an improvement on the Franklin Institute method, and is designed to show at a glance:—

1. The distribution of light in five great circles. 2. The relative position of the lamp filament to the photometer at the zero of each circle. 3. The appearance of the filament as seen from the photometer disc at the zero of each circle. 4. The rated candle-power. 5. The mean spherical candle-power. 6. The mean horizontal candle-power. 7. A table of data.

TABLE *showing Position of Lamps when arranged in order of their efficiency in watts per spherical candle-power, and other data.*

Lamp.	Voltage.	Rated c.p.	Watts per spherical c.p.	Watts per horizontal c.p.	Spherical c.p. Rated c.p. per cent.	Horizontal c.p. Rated c.p. per cent.

All of these lamps were bought in the winter of 1886-87, of supply companies in Boston, out of stock, and presumably could not in any way be picked lamps. The Edison lamps had the copper-plated shanks, and are now (1889) known as the "old lamp." The Weston 110-volt lamp is not now in the market, and I believe was on sale for only a short time after these were bought, an improved lamp taking its place. I do not know whether the 70-volt Weston lamp of the kind tested is in the market or not. The Thomson-Houston and Swan lamps appear similar to those now in the market, and are, as far as I know, the same.

A study of these tables and plots (see Plates I. and II.) will make it very evident that there is no commonly accepted value of a candle-power, or, if there is, that different makers vary widely in their attempt to produce it.

THE AMERICAN TELEGRAPHERS' FAST-SENDING TOURNAMENT.*

BY PATRICK B. DELANY.

As there are forty or fifty thousand people talking about the young Yankee Pollock, who brought his bundle of thews and nerves down from a Connecticut town, and coolly stretched the record out of each at the fast-sending tournament, we might as well see what this cheeky manipulator really did. In his first trial he poured out a stream of dots and dashes to the tune of 51½ words per minute; and then, like Mark Twain's coyote, when his speed was questioned let out another link in his backbone and shoved the record up to 52 words per minute, making 260 words in the five minutes given to each contestant. It is claimed, and with some reason, that the work was not plain and perfect. I know that the sending of Messrs. Gibson, Ayres, Waugh, and Bradt was vastly superior as to quality, and of such a character as not to fly off the poles in turning sharp angles; but still, I think, the "Yankee Blade" made all the signals, and that the lack of clearness so noticeable was, in a great measure, due to the great speed and his lightness of touch.

It has been the custom heretofore for commercial operators to turn up their noses at the railway operator, and Pollock seems to have made up his mind to avenge the slights and indignities so long and lavishly heaped upon his train-guiding brethren. Admitting that his juggling of the signals had many of the characteristics of a railway accident, still, every time I caught the thread of his discourse I found him putting it all in honestly. I couldn't follow him all through. Even the air-brakes seemed powerless to hold him. He was a sort of runaway train going down grade, and if the time-keeper hadn't opened the switch on him, there is no telling where he would have fetched up. Now, if Pollock, Jr., made all the signals, I claim that, regardless of classicality, he has performed a wonderful feat, and I am strongly of the opinion that so great a number of impulses, of any kind, have never before been made in the same time.

I have been experimenting a little since the tournament, with a view of ascertaining whether, if Mr. Pollock had made all dots, he could have crowded any more into his record than the number of mixed dots and dashes credited to him; and I have come to the conclusion that the almost infinite number of changes involved in the transmission of the English language by dots and dashes is restful to the operator, and that if he were compelled to make the letter "p" or figure "6," consisting of all dots, at top speed, for five minutes, his muscles would be practically paralysed. It is easily tried. Others may find it different.

Since Fast Sending Tournaments promise to increase in interest from year to year, I have no doubt that certain improvements will

* From the *Electrical Engineer*, New York.

Digitized by Google

be made in their arrangement which will contribute to the speed of the operators and to the certainty of decisions by the judges. Nothing was plainer than the consideration and fairness of all connected with the tournament just closed; but when writing climbs up into the fifties, it becomes very misty, and faults are difficult of detection. I have many times tested the limit of sound reading by using a punched strip and machine transmission. Sixty to sixty-five words per minute can be followed, if the matter be familiar to the ear, or with the manuscript before the listener, but this must be from a strip careful'y punched. I think, therefore, that a Wheatstone recorder should be used for receiving the writing of each contestant. This instrument, properly adjusted, will record over 500 words per minute, so that there need be no fear of anything being missed. I would suggest also that a condenser be used to prevent sparking at the key points, especially if a considerable number of sounders are to be used in the circuit. It occurred to me and some others that one first-rate sounder placed in the centre of the hall would be more satisfactory than a number scattered about, some well adjusted, others not. With a single sounder there would be a unanimity of opinion regarding the quality of the work.

An analysis of the real meaning of Pollock's wild flight is interesting. It shows that the 260 words transmitted in five minutes call for 1,223 letters and 11 punctuations, or say, 1,234 letters in all. To make these letters 2,834 impulses were required. This puts over nine impulses into each second, and as each impulse calls for a down and up motion of the key, the hand and fingers of the "Railway Guide," from Hartford, had to make nearly 19 movements per second for 300 consecutive seconds. If anyone thinks he carries more agility than this about his person, fame awaits him—if he is not mistaken.

I doubt very much if there be any one living able to write out words at this speed. Forty-five words per minute will claim any man's undivided attention, so that until the penmen can put more steam into their fingers, Pollock's gait would be useless, even if it could be maintained—which it could not. It is fair to assume, however, that a man who can do 52 words per minute in any shape, might send grandly at the rate of 45 words per minute. If the elder Catlin's pace and beautiful style of transmission were general throughout the country and there were receivers to put it down, the earning capacity of the telegraphs would be just about doubled. Here is something for managerial meditation. There is money in it. When a boy like young Catlin, not yet old enough to vote, can double the work of an ordinary circuit, he becomes a duplex. He should be encouraged.

To my mind the great speed and general excellence of the work of the young women was the most remarkable feature of the contest. It was a revelation to one who has not been very close to the sounder for some years. I considered 32 or 33 words per minute the winning speed in their class, but how the glory of old times faded when 43 and a fraction were poured out with ease and grace without untying a bonnet string. I think the quality of the young women's work averaged higher than that of the men.

I find that there are 636 dashes in the 260 words sent by Pollock, or an average of about one dash to two letters. Five letters to a word is the usual way of reckoning. If Pollock had to furnish five letters to a word, his score would be 246¼ words. But 4⅗ to 4⅞ is nearer the average. This may be proven by counting the letters and words in a few columns of the editorial page of the New York *Sun* any day.

In the first 50 words of the 260 there are 600 Morse characters; in the second 50 words, 566; in the third 50 words, 531; in the fourth 50 words, 532; in the fifth 50 words, 503, and in the 10 words which distinguished Pollock, there are 102 characters. There is a difference of 97 characters between the first 50 words and the fifth. This is equal to five words. As young Catlin sent 251 words and one letter, or 2,738 characters, he is just 96 characters behind Mr. Pollock.

There were 13 women and 34 men in the contest. Taking the highest figures of each contestant, they foot up a total of 9,955 words transmitted, or an average of nearly 42½ words per minute for each of the 47 operators. The women averaged 39⅔ words per minute, the men 43½. All praise to the ladies. Great is Pollock.

THE RAILWAY RATES INQUIRY.

This inquiry was continued on Wednesday at the offices of the Board in Whitehall, before Lord Balfour of Burleigh, and Mr. Courtenay Boyle, C.B.

Mr. STUART, on behalf of the Postmaster-General, objected to the inclusion of "telegraph poles" in the exceptional class with a minimum of two waggons and one ton per waggon for every waggon used. The railway companies contended that the Post Office was sufficiently protected by the provision that the charge must be reasonable; but that was simply begging the question, because the companies made what charge they liked, there was no means of testing its reasonableness.

Mr. TWELVETREES, of the Great Northern Railway, defended the classification on the ground that the Clearing House arrangement had been adhered to, and that the class contained other articles as well as telegraph poles, such as boilers and ships' masts, which required exceptional treatment in transit. It was necessary in many instances to use more than one waggon in carrying them. For this reason they had been put in the exceptional class.

LORD BALFOUR OF BURLEIGH said the question was not whether there should be a universal application of the classification, but whether it was the correct classification for telegraph poles. How long had the classification been in force?

Mr. TWELVETREES stated that telegraph poles had been in the exceptional class for many years, with a minimum charge of one ton per waggon.

Mr. COURTENAY BOYLE thought the argument for putting timber, such as telegraph poles, in the exceptional class was not very strong.

Mr. WILKINSON, of the Great Western Railway, remarked that he was at Reading on Saturday with Sir Douglas Galton, when he saw a consignment of telegraph poles which were so long that it required five waggons to take them.

Mr. STUART said that would be a very exceptional case. The Post Office did not object to a minimum consignment of two tons being charged. The railway companies defended their classification of copper wire on the ground that it was six or eight times as valuable as iron wire. That, however, was not the fact. Copper wire was practically undamageable, and no claim had ever been made by the Post Office for injury in transit. With regard to "telegraph wire, coated with gutta percha," He, on behalf of the Post Office, claimed that this article should be included in a lower classification. It was undamageable and easily handled, as might be seen from the manner in which it was drawn through iron tubes in the streets of London. This article was much less damageable than many of the articles already in Class 3, into which the Post Office claimed that telegraph wire coated with gutta percha should go. He further said he thought that in the case of telegraph insulators the railway companies had met all the objections of the Post Office by allowing them to go into Class 1.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 9, 1890.

The Edison Company and the Zipernowsky Alternate-Current Patents.—An interesting feature of the alternating-current squabble that has made sport for the lawyers during the last few years is a suit brought by Ganz and Co., of Budapest, against the Edison Electric Light Company. In 1886 the Edison Company obtained the American right to the Zipernowsky alternating system, paying for the same some $5,000, and agreeing, so Ganz and Co. allege, to introduce it into the United States. As is very well known, they have not done so; and now Ganz and Co. file a complaint before the United States Circuit Court, saying that the rights to the system were obtained by misrepresentation on the part of the Edison agents; that whereas an agreement was made to introduce it into the United States, so far from being introduced, it has been assiduously suppressed; therefore the complainants pray to be released from the agreement, and ask suitable damages. This is all very interesting from a legal point of view, but its exact significance in view of the present stage of the alternating current discussions, is not easy to find.

The Physiological Effects of Electrical Currents.—*Apropos* of the English experiments on the physiological effect of electrical currents, the experiments of Dr. Edward Tatum, recently published, may prove of some interest. Dr. Tatum has spent much time and care in studying the effect of both continuous and alternating currents, and the results which are reached are of importance. His experiments were tried upon dogs, and were aimed to discover the actual mechanism in producing death. This has been generally ascribed to violent action upon the nerves, especially the cerebral centres controlling the pneumo gastric system. Dr. Tatum shows very clearly that the action of the current is something more than this, and in fact makes it evident that a large part of the action is not on the brain but on the heart itself. He found it possible to pass a strong current through the head of a dog without a fatal result, while a current equally intense applied to the region of the heart produced almost immediate death. Besides this, he separated the pneumo-gastric

Digitized by Google

system from direct action on the heart by experiments on dogs that had been previously dosed with atropine or curare. In addition, in one set of experiments he completely eliminated the connection of the pneumo-gastric system by cutting the vagus nerves. Under these circumstances, the current still produced instantaneous death with the same readiness as before. With etherised dogs, he found, however, that there was somewhat greater tolerance for electric currents, particularly alternating currents, than in the case of dogs not under the influence of anæsthetics. The general tendency of his experiments is to show that the death from electrical current is due to something besides nervous shock. At the same time he effectively sets aside the sensational statements that have been made concerning alternating currents. He made no attempt to investigate the difference of mode of action which might exist between continuous and alternating currents; but his experiments are conclusive in showing that although the alternating currents certainly kill more readily than continuous, they are far less fatal than some recent experiments have led us to suppose.

CORRESPONDENCE.

HIGHER TECHNICAL EDUCATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your concluding remarks in the last issue referring to Prof. Percy F. Frankland's Paper recently read before the Society of Arts are quite to the point, and deserve to be repeated over and over again. It is very well for English professors to visit Continental "Technical High Schools," and on returning comment upon their "aim and scope," upon the elaborate teaching staff, the amount of money granted by the Governments, and the handsome buildings erected for this purpose. These numerous institutions certainly turn out thousands of what one may call over-educated youths; but let the question be asked: What becomes of all these men whose training has cost the State enormous sums of money? What is the result of this vast sacrifice of money, time, and brains? Has Prof. Frankland and the other enthusiasts taken the trouble of ascertaining the number of men who have neither the chance nor the ability of utilising their store of acquired knowledge?

If he has inquired into this he will have found that at least 70 per cent. of these over-educated youths do not follow up the theoretical training by practical applications. The vast majority take positions as clerks in the Civil Service, become soldiers in the standing army (as distinct from those who serve the compulsory term); many turn to be mercantile clerks, bookkeepers, draughtsmen, shorthand writers, railway station-masters, and perhaps tramway conductors. The few gifted ones, if they work hard after they leave the schools, unlearn much they did learn, and learn that which they ought to know in order to be useful; these few gifted ones, together with a few who have influential friends, turn out bright professional men, and are held up all the world over as samples of higher technical education. But these very men would have made their mark in any country, even in England and in America, where this super-technical-State training does not exist, provided that they had a moderately decent education to start with. Great Britain and the United States, the two countries which do not possess those higher technical institutions, after the models of Switzerland, Germany, and Austria, can boast not merely of the greatest number of first-rate engineers, but also of a preponderance of men of genius in the technical professions.

I could point out, on the Continent, some technical high schools which had 15 or 20 years ago an average of a thousand students, and which have to-day no more than 150 or 200, although in the meantime these institutions have been improved, and cost now as much, or even more, to maintain than formerly. The fact of the matter is that there are too many of these high schools; the Governments have educated more scholars than were wanted, and the supply exceeds the demand. At the same time the attendance in the technical middle schools (Realschulen and Gewerbeschulen) has steadily increased, and much of the best talent comes from these. These lower technical schools prepare boys efficiently for practical apprenticeships.

Manufacturers prefer young men who passed creditably through these lower technical and trade schools. It is perhaps natural that the student who spent several years in the "high school" (where he acquired much knowledge with little understanding) should be proud of his achievements, and assume a certain amount of conceit. But he soon finds out that he is utterly unable to earn a living, and he has in most cases to work for no salary for a year or more, after which time for another year or two he is bound to accept a miserable pittance which any skilled mechanic would be ashamed to receive. If you ask the manufacturer why this is so he will tell you that the "high school" man gets all or more than he deserves, and that he prefers the practical intelligent mechanic. Of course, there are a few instances when much theory is appreciated, as in laboratories; but these instances are rare.

It would be a great pity if such a system were initiated in this country. The City and Guilds of London and kindred institutions are on the right track; and it would be better to extend these, and uphold the sound apprenticeship system, than follow the advice of Professor Frankland and other advocates of unsound educational doctrines.—Yours, &c.,

London, May 19, 1890. A. RECKENZAUN.

THE LANE FOX DISTRIBUTION PATENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A paragraph in your issue of the 16th inst. seems to imply that Mr. Lane Fox's patent for distribution, No. 3988** of 1878, only shadowed forth the bare outline of a system the essential details of which were laboriously worked out by others. That Mr. Lane Fox did something more than this is evidently the opinion of more than one eminent authority. Sir William Thomson writes in 1886, "The system of distribution . . . is a useful and largely used invention at the present day." Prof. Perry writes in the same year, "The method described by Mr. Lane Fox is what is in use at the present time." Clearly, then, these gentlemen are of opinion that Mr. Lane Fox did something more than "shadow forth a scheme."

Passing to the latter part of the paragraph; you complain that royalties are to be exacted by Mr. Lane Fox from "those who have laboriously worked out the essential details." Let us examine how the matter really stands. Mr. Lane Fox worked out the principles; others have elaborated details. Mr. Lane Fox has, up to the present, charged nothing for the use of his patents; he now proposes charging a small royalty. The gentlemen who have "laboriously worked out the details" have charged royalties for the use of their improvements. That they had a perfect right to claim the fruit of their inventions will, I think, be generally admitted; but, granting their right; on what principle can the same privilege be denied to Mr. Lane Fox?—Yours, &c.,

C. A. STEPHENSON, Managing Director,
Lane Fox Electrical Co., Ltd.

2, Princes Mansions, Victoria Street, S.W.,
May 19, 1890.

[In the paragraph in question we did not imply that the Lane Fox Electrical Company (Limited) had no *right* to exact royalties in the event of the Patent No. 3,988 of 1878 being held to be valid, but we *did* imply that under the circumstances the electrical industry was to be congratulated upon the fact that the patent shortly expired.—ED. *E.*]

THE EFFICIENCY OF GLOW LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have a few remarks to make on the subject of your leading article "The Efficiency of Glow Lamps" (*The Electrician*, May 9th).

If instead of the words "efficiency of glow lamps" one could impress upon one's mind, what is practically an equivalent expression, *i.e.*, temperature of incandescence of glow lamps, then this subject would be more clear and intelligible. The plan in general use, at least among lamp-makers, of expressing the

Digitized by Google

rate of efficiency of a glow lamp in watts per candle-power, is all that is desirable and is practically correct enough.

A short time ago (*The Electrician*, February 28th, p. 432) I pointed out in your columns the necessity of fixing upon some recognised standard rate of efficiency (3½ watts per candle-power), and I then said this was equivalent to fixing on a standard temperature of incandescence. I would like to hear of any important objections there may be to this suggestion, for to me it seems the only practically possible one. I have also remarked in another letter (*The Electrician*, March 7th, p. 458) (which you remarked was not very clear to you), that if there were a fixed standard rate of efficiency, *i.e.* (temperature), then comparative data as to the life of lamps at any other rate of efficiency could be obtained by reference backwards or forwards to the standard rate. I find, that for practical use, the life of a lamp may be taken as about inversely proportional to the sixth power of its rate of efficiency (temperature), as compared with its life at any other rate of efficiency (temperature), which in my practice I take at 3½ watts per candle-power.

The greatest difficulty in the intelligent adoption of such an expression as the rate of efficiency of a lamp in watts per candle-power lies in the great uncertainty and variation that now exists amongst the trade as to what is a candle power. Until there be a recognised and fixed standard (such as, say, the English standard one candle-power on a Harcourt-Pentane lamp), all such expressions as above are useless. I find these variations especially in my practice here on the Continent, where lamps from various makers are in use; and I have to use reduction tables to find what are the actual volts, amperes, candle-power, watts per candle-power, &c., of the other manufacturers as compared with my own legal volt and ohm and the English standard one candle-power. In one factory the English one candle-power Harcourt-Pentane standard is used; in another, the Carcel burner; in another, the German standard sperm candle; in another, the Hefner-Altneck amyl-acetate lamp, with a flame at 40mm. high; and so on. Hence can be seen what complications, uncertainties, and variations are likely to arise in the intermixing of such variously-tested lamps. It is this great variety in the units of light that will alone account for the large variations in the watts per candle-power that Mr. Puffer has observed.

The most important object for a lamp manufacturer to keep in view is to have well-recognised exact standards, such as the legal ohm, the legal volt, and Harcourt's Pentane lamp, and then to turn out lamps all running at the same rate of efficiency in watts per candle-power (*i.e.*, temperature). With a reliable wattmeter this becomes an easy matter, and the naked eye is in itself a wonderfully exact judge of the comparative efficiencies of lamps. For instance, having two lamps of the same dimensions, surface, &c., then a trained eye can observe a difference of one volt in a 100-volt lamp. Reading from my notes I see that this would be judging within ¼ of a watt per candle-power (0·25 watt per candle-power), so that having fixed standards a trained eye could always prevent variations in the rate of efficiency inside of 0·25 watt per candle-power, and this would mean that lamps would be sent out having a definitely fixed temperature, although they might vary among themselves as to their actual candle-power. When, on the other hand, the eyes come to observe candle-power at different rates of efficiency (temperature), then the variations likely to arise are enormous and very misleading.

It is easy to see that variations in candle-power among the lamps comprised in any particular installation are not of such paramount importance, but that very great exactness in their rate of efficiency (temperature) is necessary, and that this is, *cæteris paribus*, the best means of ensuring similarity in and length of duration.

I must take objection to your remarks "that the manufacturer of glow lamps is far from equalling the dynamo maker in being able to turn out a large number of articles which are all practically identical." If you had said, "the manufacturers of glow lamps are far from equalling the dynamo makers, &c.," then I would heartily agree with you, and I have above pointed out the causes tending to this present state of things; but I, as an individual manufacturer, find no difficulty whatever in turning out any number of lamps which are all practically identical and well within the percentage of accuracy a dynamo-maker would be satisfied with. It is a daily practice to turn out lamps for a particular order, having a maximum variation of less than ½ in their candle-power, ¼ in their watts per candle-power, and 1 per cent. in their voltage; and this order can be repeated at any future date with the same accuracy.—Yours, &c.,

C. J. ROBERTSON, A.I.E.E.

Middelburg, Holland, May 13, 1890.

ELECTRICAL TRAMWAY SYSTEMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read Mr. Allsop's letter in your last issue, and have obtained copies of the specifications to which he refers. We observe that Mr. Allsop finds it difficult to see any new points in our system; and we are not surprised at this, if, as would appear from his letter, and indeed from his specification, Mr. Allsop attaches no importance to mechanical details, which he thinks may be entrusted to any mechanic. In our opinion, and we would venture to say in the opinion of engineers at large, a successful invention is not so much dependent on a happy idea as on the careful consideration and working out of the many details essential to enable such an idea to be put into a practical working form. It is to these essential details that we have devoted our attention; and, notwithstanding Mr. Allsop's opinion to the contrary, we still think that our system is very far from being identical with that which he proposes.

It is unnecessary to enter into a lengthy controversy in your columns in regard to the differences between Mr. Allsop's system and our own; and so far as your readers are concerned their interest will naturally be confined to an examination of the practical merits of the system, and the relative merits of our respective claims can have no bearing on this side of the subject.—Yours, &c.,

J. EDWARD WALLER.
E. MANVILLE.

Princes Mansions, 68, Victoria-street, Westminster,
London, S.W., May 20, 1890.

LIGHTNING PROTECTOR DISCUSSION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am a little surprised to learn from your editorial remarks this week that Prof. Hughes' observations in the recent discussion at the Institute of Electrical Engineers conveyed the impression that the principle of my lightning guard had already been unconsciously applied. I did not remember hearing this maintained; but when my Paper is published I imagine it will be clear that it is certainly not the case.—Yours, &c.,

OLIVER J. LODGE.

LEGAL INTELLIGENCE.

Shangan v. Metropolitan Electric Supply Company.

This was a motion which came on before Mr. Justice North on Friday last for an interim injunction to restrain the defendant company from continuing to create a nuisance by noise in conducting the operations of building and constructing electric lighting works. The plaintiff was a lodging house-keeper at 11, Manchester-street, Manchester-square. The defendants were constructing an establishment for electric lighting in the rear of the plaintiff's premises. There was evidence on the part of the plaintiff to show that there was an intolerable nuisance, and that he was likely to lose his lodgers and have his business affected. The defendants attempted to show that any noise made by their workmen was so trivial that it could not affect any one except a nervous person.

Mr. Justice NORTH said that persons living in a populous district must submit to a certain amount of inconvenience from the acts of their neighbours. He did not see any reason for interfering with what the defendants were doing in the daytime. He was satisfied, however, that what had been done during the two hours between 6 and 8 in the morning was more than a neighbour should reasonably be called on to endure. He therefore granted an injunction limited to that period of time.

In re International Cable Company (Limited).

On Saturday last Mr. Justice STIRLING delivered judgment in this case (see *The Electrician*, May 9th, p. 15). After going minutely and at very considerable length into the facts and evidence applicable to the case,

Digitized by Google

he came to the conclusion that he ought not to hold that the concession had lapsed, and that no renewal of it could be obtained. There was some evidence, he said, that the concession might be extended, and that, so soon as the Halifax-Azores section of the cable was laid, the capital for constructing the Lisbon-Azores section would be obtainable. Since 1889 the attention of the directors had been mainly turned to the Halifax and Bermuda cable, which was in course of being laid, and it was possible that the existence of this cable might favourably influence the Portuguese Government. In the face of these considerations, his Lordship could not come to the conclusion that the negotiations had come to an end, and that the petitioner was entitled to an immediate order; and, as the Company desired delay, he should order the petition to stand over until the third petition day in July next.

Reece v. Latimer Clark, Muirhead, and Co.

In the Westminster County Court, on Monday, his Honour Judge Bayley had before him the case of Reece *v.* Latimer Clark, Muirhead, and Co., which was an action to recover damages for injuries sustained by the plaintiff through the alleged defective condition of a drilling machine.

On January 16th of this year the plaintiff was cleaning out the base of the machine prior to using it, when, without any warning whatever the drill came rapidly down, and pierced his hand, inflicting very severe injuries. Several fellow-workmen who were, at the time of the accident, in the employ of the defendant firm, were now called by the plaintiff, and were unanimously of opinion that the machine in question was in a dangerously defective state; but although that was so, they never thought it worth while to make any complaint, as they did not think it their duty to do so.

For the defence, Mr. JAMES PULLEN was called, and said he was the defendants' foreman. Up to the time of the accident he never heard a single complaint made about the machine, although it was constantly in use. It had been at work for some five years, and was as good now as when new. Like all other machines it required a little care and attention, and then it was all right.

Mr. JOHN FARQUHARSON was called, and said he was an electrical engineer at Sheerness Dockyard, and was well acquainted with all kinds of machines. He had examined the machine in question since the accident and had found it in every respect to be in a thoroughly workable condition. The working of the machine was governed by two screws, with which it was fitted and had they been judiciously made use of, he did not believe the accident would have happened.

In giving judgment, his Honour said that after hearing the evidence for the defence, he was quite satisfied that the machine was not defective, and that if properly used it was perfectly safe; therefore the verdict must be for the defendants.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

More Warnings.—We had occasion last week to caution our readers against a person who is imposing upon members of the electrical trades by securing goods on fictitious orders. This week we are asked to warn our readers against a foreigner representing himself to be in possession of a valuable primary battery invention, but in need of a little ready money to make up a sample. This individual pretends to be a Doctor of Physics of Vienna, and speaks but little English. He is described as young, tall, with black hair well combed down over the forehead, and with a well-developed "port-wine" mark on one cheek.

———We are ourselves also aware of another case in which a Pole is the inventor of a "new" arc lamp, and only wants a small amount of capital to enable him to bring it out. As this gentleman's "invention" is a clear infringement of an existing British patent, we warn our readers against his specious overtures.

Electric Light Cable for Sale.—In our advertisement columns will be found particulars as to 1,570 feet of electric light cable for sale, offers for which are to be sent to "The Exmouth Committee," Metropolitan Asylums Board, Norfolk House, Norfolk Street, W.C., before Saturday, the 31st inst.

Electrical Block Signal Appliances for Sale.—The Lancashire and Yorkshire Railway Company notify through our advertisement columns that they have a quantity of these appliances for disposal. Particulars will be furnished on application to Mr. J. A. F. Aspinall, Chief Mechanical Engineer of the Company, Horwich, near Bolton.

The Fire at Messrs. Robey's.—Messrs. Robey and Co. write us that none of their workmen will be out of employment, nor will any stoppage of business be caused by the fire which occurred at their works on Wednesday last.

Personal.—Mr. W. Moore, engaged in the electrical shop at Devonport Dockyard, has been appointed to proceed to Malta to take charge of the electrical fitting shop there.

Mr. Gladstone's Visit to Norwich.—On the occasion of Mr. Gladstone's visit to Norwich on Saturday last, the large Agricultural Hall was lit by electricity by Messrs. Laurence, Pari*, and Scott, under the superintendence of Mr. W. B. Sisling.

Mr. F. N. Newton.—Mr. Newton notifies us that, owing to the growing requirements of his business, he has been compelled to take larger premises, under the style and title of the Newton Electrical Engineering Works, Taunton, where he has removed from Barton Grange.

Mr. H. A. Henderson.—Mr. Henderson notifies us that he has devised a new method of fitting up small houses with electric bells. The prices quoted in the circular before us are very reasonable.

White's Patent Divided Wire Ceiling Rose and Pulley Attachment.—This is a ceiling rose especially designed to avoid any possible chance of the wires getting short-circuited inside the cover. The base and cover are made entirely of porcelain. A conical pillar stands up from the base, and is part of the base itself,

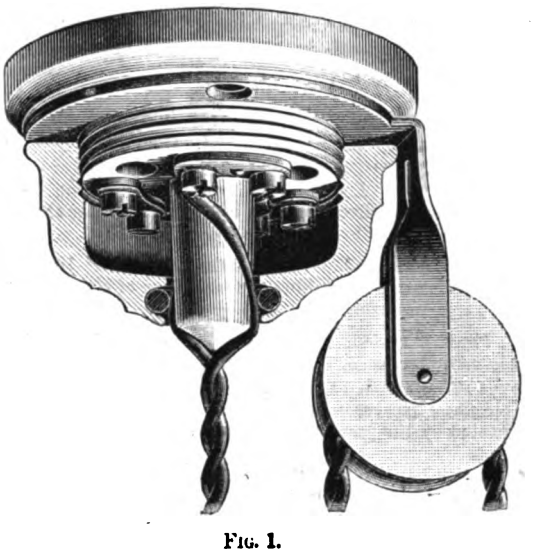

Fig. 1.

and is also made of porcelain; on opposite sides of this pillar are two spiral grooves cut in the porcelain, and running from the base

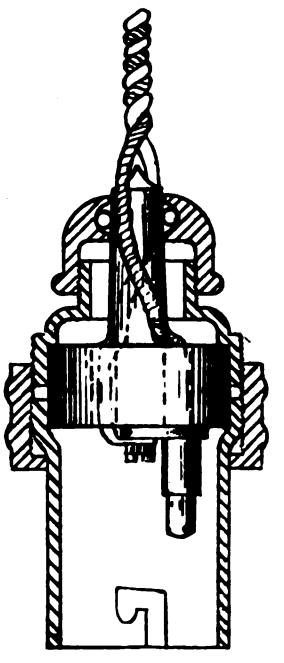

Fig. 2.

to the top of the pillar; in these grooves the branch wires leading off to the lamp are laid, and are held in place by means of a rubber ring, which fits in the hollow left for it in the cover, as will be seen by Fig. 1. The same device of a conical pillar and rubber ring is also applied to suspension holders for the same purpose as in the ceiling rose as shown in Fig. 2. The special advantages claimed by the makers are that by

Digitized by Google

this means the wires are kept quite separate until after they have left the ceiling rose or holder; that there is absolutely no weight on the terminals; and that no dust whatever can get inside, as the rubber ring grips the wire tightly, and so takes all the weight and keeps out the dust. The pulley attachment shown in Fig. 1 is a cheap means of attaching a pulley to a ceiling rose; the pulley holder itself being made of a brass stamping, and bent up as shown in the illustration. The attachments are made in several sizes by Messrs. Poole and White, of Bread-street, Cheapside, E.C.

MESSRS. APPLETON, BURBEY, AND WILLIAMSON.—This firm notify that they have purchased the manufacturing business of Mr. F. Geere Howard, and have transferred the plant to their works at Hatton-garden, E.C.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

COMPANIES' MEETINGS.

The Panulcillo Copper Company (Limited).

At the twenty-seventh ordinary general meeting of this Company, held at Winchester House, E.C., on Tuesday last, the CHAIRMAN (Sir John Pender, K.C.M.G.), in moving the adoption of the report and accounts, referred to the anxious period they had recently gone through. Since then there had been considerable changes, and at the present moment the Company stood in a position to take a calmer and more correct view of copper than they have been able to take at any time for a considerable period. At the last general meeting they were in the midst of the crisis produced by the collapse of the copper syndicate, and in addressing the shareholders then he said that "there could be no question that the very large and sudden fall in copper prices had placed them in very great and serious difficulty, as some time must elapse before costs in Chili could be adjusted to the low values here, and that in the meantime it had been necessary to stop smelting." It was this unfortunate state of things which led to the heavy loss in the first six months of the year now under review, In the second half the ill-effects still continued, but they were so far mitigated that after August the Company ceased to lose money, and were able to record some profits. The gain, however, in September and October only amounted to £416. In November the profit was £963, and in December it reached £1,422. These December results showed that a satisfactory proportion had been established between Chili and Europe, and that all that was required was a sufficient supply of outside ores to mix with the valuable flux afforded by the Panulcillo sulphurets. It was the want of these outside ores which had crippled their operations, for they would observe from the mining report that the position of their own mines was very hopeful, the supply in the past six months having been 161,000 quintals, against 146,000 quintals in the corresponding period of 1888, while the reserves at the close of 1889 were estimated as 863,000 quintals against 732,000 quintals in 1888, showing an increase of nearly 20 per cent. With the hopeful reports on their mines, and with the price of copper in Chili advanced by the last cable advices to $22 per quintal, the only point that troubled the Directors was a full supply of carbonate ores; for without such a full supply they could not make large profits; but with it he saw no reason why they might not look for a repetition of the prosperity of 1880-83, when, having realised sufficient to wipe out the previous heavy loss of capital, they made profits amounting to £121,000. These profits were made when the Company was subject to debenture interest, and when the average price in Chili was about $19, against $22 by last advices. The aim, and he might say the necessity, of the present day in all manufacturers is to combine in one undertaking all the processes of manufacture, and by amalgamations, or otherwise, to work on the largest scale, thereby reducing the incidence of general charges, and securing all the profits each trade can give, at the same time that it allows of the employment of the most scientific processes and management, which might otherwise be found too costly. An opinion he recently gave was that the depression in copper was exaggerated, and that with an expanding consumption, and no reserves of old copper, there would be no difficulty in establishing the value of Chili bar copper at about £50 per ton. The price now was considerably above this figure, with the prospect of some further advance. He could not do better than refer them to an article on copper, which appeared in *The Statist* of 19th ult. These views are supported by some very interesting remarks from the American correspondent in last Saturday's *Statist*. In conclusion he ventured to express the hope and belief that they were on the point of leaving all their difficulties behind them. In acknowledging a vote of thanks, the Chairman said the new market which was opening in electric lighting would undoubtedly make a great demand upon copper stocks—in fact, he knew from personal experience that there was an enormous future before the electric light, which could not be established without copper. These were facts which warranted the shareholders anticipating a growing market for the Company's products.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended May 16th amounted to £3,765.

COMMERCIAL CABLE COMPANY.—It is announced on behalf of this Company that at a Board meeting in New York, on Monday, the following were elected Directors:—Sir Donald A. Smith, K.C.M.G., Mr. W. C. Van Horne, Mr. C. R. Hosmer, and Mr. Thomas Skinner (London).

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The ninth ordinary general meeting of this Company takes place on Thursday, the 29th inst., at Cannon-street Hotel. The Directors' report and accounts will be issued next week.

DEVON AND CORNWALL ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company announce the issue of 14,900 ordinary shares of £5 each, and 100 founders' shares of £5 each. The ordinary shares are payable: 10s. on application; 10s. on allotment; £1 on August 1, 1890; £1 on November 1, 1890; and the balance, in instalments not exceeding £1 per share, at intervals of not less than three months. The founders' shares are to be paid in full on allotment. This Company has been formed for the purpose of establishing, in the principal towns of Devon and Cornwall, central stations, at which electricity can be generated on a large and economical scale. The first centre of the Company's operations will be Plymouth, from which the Company expect a considerable revenue. The station will be of similar construction to that of the House-to-House Electric Light Supply Company at Kensington; but the Company will be perfectly free to acquire and use any improved apparatus or method. The prospectus further states that the Directors have obtained the consent of the local authority at Plymouth to the granting, by the Board of Trade, of a Provisional Order to the Company. The subscription list opened on Tuesday last, and closes this day (Friday), at 10 a.m. The Secretary (*pro tem.*) is Mr. George Murray, and the temporary offices are at 2, Courtenay-street, Plymouth.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The prospectus of this Company was issued yesterday (Thursday). The capital is £200,000 in shares of £5 each, of which 100 are founders' shares and the balance ordinary shares. The present issue is for £100,000 in ordinary shares, and £500 in founders' shares. The latter have already been subscribed for, but no preference is to be given to the holders of the founders' shares in the allotment of 20,000 Ordinary shares now being made. 10s. per share is to be paid on application, and 10s. on allotment, beyond which no call is at present to be made. The Chairman of the Company is the Duke of Marlborough, and amongst the Directors is Mr. Emile Garke, the manager of the Brush Company. The Secretary is Mr. J. Cecil Bull, and the offices are at 1 and 2, Great Winchester-street, E.C. The prospectus states that the Company has been formed primarily for the purpose of facilitating the promotion and development of undertakings for electric lighting, traction, transmission of power, and for other industrial uses of electricity. The Company has no intention to compete with the existing electrical firms and companies, but to aid and assist them in developing an industry which at present has practically an unbounded scope. The Company does not propose to manufacture any electrical appliances. The principal sources of profits are expected to be commissions on underwriting; profit on acquisition and realisation of concessions, &c.; remuneration for services in examining, reporting on, and assisting the promotion and development of electrical undertakings. The subscription list closes this day (Friday) at four p.m. for town and country.

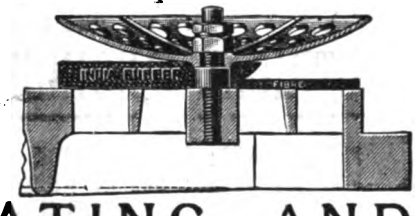
FERRO-TYPE AUTOMATIC PHOTOGRAPH COMPANY (LIMITED).—This is the name of a new Company about to be launched with a capital of £75,600 in £1 shares. Amongst the advantages claimed for the Company's process is that the electric light is applied automatically to the "penny-in-the-slot" machines, so that photographs can be taken by night as well as by day.

HORNSBY AND SONS (LIMITED).—The following interim dividends were declared at a meeting of the Directors:—2s. 9d. per share on ordinary shares for the half year ended March 31, 1890; and at the rate of 6 per cent. per annum on Preference Stock for the half year ended June 14, 1890, both payable on June 14th.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 16th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,896.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 20th Sept. 1886.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 628.—Vol. XXV. FRIDAY, MAY 30, 1890. Price Fourpence.

NOTES.

The Intercolonial Conference on Postage and Cable Rates has agreed to Sir John Pender's latest proposal in respect to the Australasian cable rates, namely, 4s. per word for ordinary telegrams, 3s. 6d. per word for Government telegrams, and 1s. 10d. per word for Press telegrams. The only point which now remains to be settled is, whether or not the Imperial Government will share the cost of the subsidies and guarantees payable by the Colonies to the Companies. We trust that an arrangement of such supreme importance to the mercantile community, and which has been carried through so far in such a satisfactory manner, will not be allowed to end abortively on account of the comparatively minor point still at issue.

Our esteemed contemporary the *Electrical World* of New York is considerably alarmed at a carbon brush patent which has been issued to Prof. George Forbes by the United States Patent Office, and is of opinion that it "opens up as magnificent a field for interference suits as the most litigious inventor could desire." The English patent is No. 1,288 of 1885, and states that with a view of diminishing the friction and consequent wearing away and heating which generally result when contact is made by metal surfaces in relative motion, it is proposed to employ carbon blocks; plates, such as are used in galvanic batteries, with a backing of copper, being preferred. The claims are four in number, the last being for "the combination with a dynamo machine of a collector, consisting of a surface of carbon and a metallic surface maintained in electrical connection therewith, whilst the said surfaces are in rapid relative motion."

The Halifax-Bermuda cable which was shipped away from the Thames one day last week takes with it the best wishes, not only of its friends and promoters, but of all well-informed and patriotic Englishmen. Two important naval and military outposts of the British Empire will, if the enterprise succeed, be linked together, with great advantage to their mutual security, and perhaps also a little to their commerce. But as regards the latter a lively imagination is required to discover ground for large expectations; the *Morning Post*, however, is equal to the task. Commenting on the probable results of laying this cable, our contemporary reminds us that a good deal of garden-stuff is grown in Bermuda, and that a famous lily flourishes there, the bulbs and blossoms of which are in much demand. The climate also is said to be good for sick Americans; and although it cannot be exported for their benefit they can be imported into it, and will be attracted to it the more by being able to send cablegrams homewards. We sincerely hope so; but, if we were a shareholder, our chief reliance would be placed on the £8,000 a year subsidy.

In 1887 M. Paul Janet showed that cylinders of steel, along which strong currents had been passed, became permanently magnetised transversely. By extending the experiments some very striking results have been recently obtained by M. Decharme, who has described them in the *Comptes Rendus* and *La Lumière Electrique*. The cylinders used were split longitudinally; and, after the passage of the current, the magnetism of the parts was tested by iron filing figures. It was then evident that not only was the iron magnetised transversely, but the intensity of the magnetisation varied in a regular undulatory manner along the bar, the lines of force arranging themselves in somewhat the same way as fine powder in a vibrating tube. The effects could not be accounted for by supposing the iron heterogeneous, because the nodes and loops occurred at about the same distance for different bars of various diameters and lengths. M. Decharme concludes that there is a great difference in the magnetisation of an iron core by a steady current passed through a solenoid surrounding it, and that of an iron bar through which a current actually passes. In the latter case, M. Decharme considers that the current is propagated in waves during the very short time necessary to produce the magnetisation, and compares the phenomenon with the well-known undulatory magnetism produced by the oscillatory discharge of a Leyden jar. The effect is probably due to the starting of the current, and it is therefore unfortunate that no particulars are given of the manner in which this was done—whether switched on suddenly or increased very gradually to its full value. In the latter case, no effect might have been produced, as strong currents were needed to show the phenomenon. The experiments of Blaserna have shown that undulations do actually occur for the first few moments after starting a current, and it is possible that these may be much accentuated when part of the conducting circuit is of iron. The experiments are of interest because they suggest that many phenomena usually attributed to want of homogeneousness in iron may really be due to successively starting and stopping a magnetising current.

A NEW form of electric chronograph, due to the Rev. F. J. SMITH, is described in the May number of the *Philosophical Magazine*. The instrument is original in many respects, although the time traces are made by means of electro-magnetic styli, as is the case in many other forms of time-measuring apparatus. The principle involved in the construction is that of ATTWOOD'S machine. A carriage, to which a sheet of smoked glass is attached, is impelled horizontally by means of a cord attached to a weight. The weight, after acting through a certain length of fall, is arrested by means of a table of adjustable height, and the carriage moves on with an acquired velocity which is found experimentally to be constant during the whole length of a trace.

FOR the details, which are of an elaborate character, and have been worked out with great care, we must refer our readers to the original article. There are, however, some points deserving of special mention. A serious source of error arises in nearly all chronographs in which electro-magnets are used for making the records, and is due to the fact that the armature does not detach itself immediately on the stoppage of the magnetising current, or even at a constant period afterwards. The interval of time in some cases, where much iron is employed, may be as much as 0·04 second, and Mr. SMITH found that two apparently similar magnets differed in their action by some hundredths of a second. This difficulty has to a great extent been surmounted by properly proportioning the dimensions of the core and yoke, by carefully selecting the material of the core, and by modifying the winding. After much experimenting it was found that the yoke should be made large compared with the cores, the proportions finally adopted being 2 mm. diameter and 10 mm. long for the cores, and 5 mm. square by 20 mm. for the yoke. By these means the time interval, to which the appropriate name of *latency* has been given, was reduced to 0·0003 seconds, and, what was even more important, the interval was found to be the same for different styli constructed on the same lines. The reduction of the latency not only removes an uncertain source of error, but renders the marking more definite and readable, so that the accuracy of the apparatus is much increased.

THE method by which the time traces are preserved also deserves mention. No injury to the traces was found to occur when the smoked glass was covered with photo varnish, provided first a mixture of the varnish with 25 times its volume of strong methylated spirit is poured over the plate and allowed to dry. After the application of the thicker varnish the traces can be used as negatives in the usual way.

IN our list of new companies this week will be found one entitled the General Electric Power and Traction Company, which proposes to work under agreements with the Electric Traction Company, Messrs. Immisch and Co., and the Electric Construction Corporation. Is it too much to hope that some solid progress in electric traction will result from this rearrangement?

Canterbury.—The Town Council have determined to apply for an electric lighting Provisional Order.

Electrical Execution.—The Supreme Court of the United States has refused an application for a writ of error in the Kemmler electrical execution case.

The International Telegraph Conference.—On Wednesday evening Sir John Pender gave a dinner to the delegates of the Conference at the Pavillon d'Armenonville.

Electrical Bills in Parliament.—The North Metropolitan Tramways Bill and the City of London and Southwark Subway Extension Bill were read a second time in the House of Lords on Thursday last week.

Civil and Mechanical Engineers' Society.—A visit was made by this Society to Henley's Telegraph Works at North Woolwich on the 16th inst., and the visitors were shown the whole operation of cable making.

Military Telegraphy.—Orders have been given from the War Office for the Telegraph Battalion of the Royal Engineers to form a camp at Lyndhurst during the summer, and the Army Reserve Telegraphists attached to the Post Office Volunteers have been directed to join the camp by successive parties.

Weston-super-Mare.—The Western Counties Telephone Company are making rapid progress with their work in Weston-super-Mare. Thirty subscribers are already connected with the central exchange, and in the course of a few weeks the trunk line, which will connect Weston-super-Mare with Bristol and other places, will be complete.

Post Office Jubilee Conversazione.—Arrangements are being made for holding a *conversazione* at the South Kensington Museum on Wednesday, July 2nd, in aid of the Rowland Hill Benevolent Fund, and in celebration of the Jubilee of Uniform Penny Postage. The 2nd of July will be a general holiday in the Post Office, so far as the due administration of the public service will permit.

Charging Accumulators by Alternating Currents.—At the meeting of the Elektrotechnischen Verein on April 22nd, Dr. Föppl, of Leipzig, gave a description of an apparatus for charging accumulators by alternating currents. The apparatus has a shaft revolving in synchronism with the period of alternation, which at every instant throws into circuit a certain number of the secondary cells.

Cambridge.—The Town Council have taken the first step towards carrying out the powers with which they have been invested by the Provisional Order granted them by the Board of Trade. On the recommendation of the Electric Lighting Committee, they have resolved to enter into a provisional agreement for the purchase of a site, at a cost of £1,041, on which to erect a central station.

Electric Car Statistics.—It is worth noting that the four electric cars running on the Barking-road for the North Metropolitan Tramway Company, carried on Monday last 8,689 passengers, an average of 2,172 per car, and earned £9. 1s. each. During the three days, Saturday, Sunday, and Monday 20,104 passengers were carried, which, we understand, is the highest record of the Company for this section of their line.

Heavy Thunderstorms.—During a terrific thunderstorm at Barnstaple last Sunday Holy Trinity Church was struck by lightning, one of the pinnacles of the tower being overthrown. A similar occurrence took place at Holsworthy, Cornwall. The lightning displaced the north pinnacle of the tower of the parish church, and portions of the *débris* fell through the roof. A few miles from Exeter several houses were struck and cattle and sheep were killed by lightning.

The Clerk-Maxwell Scholarship.—The amount bequeathed to the University of Cambridge by Mrs. Clerk-Maxwell, to found a scholarship in the Cavendish Laboratory at Cambridge, has been realised, and shows available for this purpose £5,963, with accruing interest on the sum of £5,000, on deposit with the National Bank of Scotland. The scholarship will be founded for the advancement of original research in experimental physics, and especially in electricity, magnetism, and heat.

Woking.—The Parochial Committee of Woking have decided to ask the permission of the Rural Sanitary Authority to enter into negotiations with the local Electric Lighting Company,

Digitized by Google

with a view of coming to some arrangement for the lighting of the streets. The Company have offered to erect and maintain, free of cost to the Authority, lamp-posts and supply current for 16 candle-power lights at a cost of £3. 10s. per lamp per annum; not less than 50 lamps to be taken in the first instance.

Telegraphic and Telephonic Extensions in Germany.—A State grant of 8,000,000 marks has just been made for the extension of the telegraph and telephone lines in the German Empire. Of this, 3,099,550 marks are to be devoted to the town telephones already existing, 606,000 marks to the erection of new ones, 1,928,000 marks to new telegraph lines, principally in the country, 761,900 marks for improvements in, and 87,500 for extensions of the pneumatic postal services in Berlin and Hamburg.

Bicycles for Telegraph Messengers.—The Postmaster-General is said to be greatly struck with a suggestion which has reached him for the improvement of our telegraphic service, this being to the effect that for the readier delivery of telegrams the boy messengers should use bicycles. The scheme would not (as the London correspondent of the *Birmingham Post* reminds us) be very suitable for cities having roughly-paved streets; but in London, where there is so much wooden pavement, it might answer very well. Several telegraph messengers in the metropolis have, indeed, already experimented with bicycles on their own account.

Report of the Comptroller-General of Patents.—The report of the Comptroller-General of the Patent Office on Patents, Designs, and Trade Marks was published on Wednesday in the form of a Parliamentary Paper. The number of applications for patents in 1889 was 21,008, as against 19,103 in 1888, and 17,110 in 1884. The receipts from patent fees during 1889 were £151,794. 4s. 4d. The total receipts were £172,820. 18s. 6d. The expenses amounted to £79,286. 9s. 9d., of which the two chief items were £49,086. 0s. 11d. for salaries and £18,200 for printing and lithographing. The surplus for the year was £93,534. 8s. 9d.

The Lane-Fox Patents.—The Lane-Fox Electrical Company have commenced negotiations with various supply companies with a view to the granting of licences and the payment of royalties under the electrical distribution patents held by them. Three methods of payment are proposed:—1. By a charge of 1d. per Board of Trade unit supplied to consumers. 2. By a charge of ½d. per unit, such payment to continue after the expiration of the licence for such a term as would render the payment equivalent to No. 1. 3. By a capitalised sum, payable partly in cash, partly in shares. An indemnity is also offered for having used the patents prior to December 31, 1889.

The French Exhibition.—As we mentioned some time ago the lighting of this Exhibition has been entrusted to the Gülcher Company. Steam is supplied from three 40 horse-power nominal Davey Paxman boilers, to two Davey Paxman engines of 200 and 130 horse-power respectively, and to a 80 horse-power Ruston and Proctor engine. The power from the engines is transmitted to countershafting. There are ten dynamos in all, namely, four 40-unit Battersea compound-wound dynamos, four 20-unit Battersea dynamos, one 2-pole 20-unit machine, and one 4 pole 30-unit machine. The lamps are all arranged in parallel, on 70-volt circuits, resistance coils being placed in series with each lamp.

Bolton and its Electric Lighting.—It is scarcely to be wondered at, says the *Electrical Review* of New York, that electric lighting does not make more rapid progress in England than has been the case hitherto. The Corporation of Bolton, a thriving industrial town in Lancashire, recently issued 1,178 circulars in connection with the proposed introduction of the electric light. Only 449 replies were received; of these but 45 (including one very large and important firm) desire the electric light; 24 wish for it if the price is the same as gas; 56 are uncertain by reason of the cost; 30 are doubtful, and 314 convey an absolute negative. In face of such deadly conservatism as this, what can electricians do?

The Clermont-Ferrand Electric Railway.—This line, which is about four and a-half miles long, connects Clermont-Ferrand with Royat-les-Bains. The cars are 40ft. long, and carry 50 passengers; they are worked by 40 horse-power motors, Vaucanson chain gearing being used. The current is supplied at a difference of potential of 300 volts. An overhead conductor run on 26ft. iron posts with rail return is used. This conductor is a slotted copper tube of rectangular section, and is supported by a ·8in. steel cable. The sliding contact is 16in. long, and consists of a string of bronze balls connected to one another and to the car by a metallic wire. The line is a single one, and passing places are provided at each of the six intermediate stations.

Arc Light Formula.—Mr. Tischendörffer, of Vienna, gives a formula for the relation between current and lighting power for arc lamps. He says that L being the lighting power, and C the current, $L = 100\left\{C + \left(\frac{C}{4}\right)^2\right\} - 200$. This gives the following values:—

C	L	C	L
2	25	16	3,000
4	300	18	3,625
6	625	20	4,300
8	1,000	30	4,825
10	1,425	40	13,800
12	1,900	50	20,425
14	2,425		

The Lighting of the Paris Exhibition.—During the Paris Exhibition M. Brault with a Weber photometer, and MM. de Nerville and Lepage with a Mascart photometer, made a number of photometric observations, in order to arrive at the actual average luminous intensity in various parts of the Exhibition. On the floor of the Palais des Machines the average intensity was 3 carcels per square metre (1 carcel per square metre = ·9 candle-power per square foot) according to M. Brault, and 1·97 carcels per square metre according to MM. de Nerville and Lepage. Under the central dome the average intensity was ·5 carcel per square metre; in the entrance-hall of the Palais des Machines, ·3 carcel per square metre; in front of the cafés and restaurants, 1 carcel per square metre; at the Porte Rapp, 7 carcels per square metre. In the gardens the average estimated intensity was only ·1 carcel per square metre.

"L'Elettricita."—In answer to the questions recently propounded by the editor of *L'Elettricità* Prof. Elihu Thomson replied that the most important discovery during 1889 was that of Hertz. In the present year he believed that the application which will receive the greatest amount of attention will be electric traction, and the transmission of energy. Dr. O. Fröhlich confessed that he did not like to risk an answer. He had always, he said, found it impossible to predict developments in electricity. Prof. Houston thought that the answer to question 1 was to be found in the improvements that have taken place in accumulators. With regard to question 2, he considered that distribution systems and the direct production of electric energy from coal would make the greatest progress. M. Maurice Levy was of opinion that the Desrozier dynamo would make the greatest progress. Among the answers published there were no English and only one German name.

Conference of Telegraphists.—On Wednesday night a meeting of the telegraph staff of the London Post Office was held in the Foresters' Hall, Clerkenwell-road, to make arrangements in connection with the Conference of the Postal Telegraph Clerks' Association, to be held at Leicester on Saturday. The first resolution which was passed provided that ten delegates should be sent to the Conference from London, six male and two female members of the Central Telegraph staff and two from the Metropolitan district offices. As a proposition to be submitted to the Conference, a resolution was adopted to the effect that, as the Postmaster-General now stated that he brought no charge against the men exiled from Cardiff, a united request, signed by every member of the Association, should at once be made to the Postmaster-General for their reinstatement. During the evening a telegram was received from Sir John Puleston, expressing gratification that full pay on sick leave had been conceded.

University College, Cardiff.—In connection with the advertisement, which will be found in another column, with regard

Digitized by Google

to the Professorship of Mechanical Engineering, about to be established at the University College of South Wales and Monmouthshire, Cardiff, we understand that the Council have been anxious since the opening of this College in 1883 to add a Department of Engineering which should be worthy of the great interests in its immediate neighbourhood. Thanks to the generosity of the Drapers' Company and of several prominent local men, this scheme will now be realised. Besides the appointment now advertised we learn that a Lectureship in Mining Engineering will also shortly be established. Electrical engineering is also to receive attention; and in order that this may be done in a thoroughly practical manner it is intended to provide a miniature central lighting station. It is expected that the above arrangements will be sufficiently advanced to enable a start to be made in October next, and it is hoped the number of students in attendance at the various classes will amply justify the Council in the course they have taken.

The Schiseophone.—This instrument, which is due to Captain du Place, is, like the "electric acoumeter" described in our issue of May 23rd, merely a modification of Prof. Hughes' sonometer. The object of the schiseophone is to facilitate the detection of flaws in metal bars, &c.; and according to our French contemporaries some recent trials of this apparatus at the Ermont workshops of the Northern Railway of France have proved it to be practically useful. The instrument comprises a striker and an audiometer. A steel rod is moved to and fro in front of a microphone, periodically striking the metal bar under examination. Two coils, one movable and connected to the microphone, the other fixed and connected to two telephones, are arranged on a graduated rod. Having placed the movable coil so that the telephones are silent so long as the hammer is striking a solid portion of the metal, the hammer is moved along the bar, and should there exist a flaw in it the increased noise given out causes more powerful currents to flow in the microphone circuit, with the result that the telephones are no longer silent.

Paddington Vestry.—A special meeting of this Vestry was held on Thursday to pass the resolution required by the Board of Trade prior to the Board formally granting a Provisional Order to the Metropolitan Electric Supply Company. Mr. Mark H. Judge contended that the meeting was not called in accordance with the rules of the Board of Trade, and asked the Chairman to rule it out of order. After some discussion, the Chairman ruled that the meeting was properly called. On the resolution being put 37 voted for and 19 against it.—A further special meeting, called by Mr. Mark H. Judge, Mr. C. A. Stephenson, and others, was then held, the notice calling the meeting to take into consideration the result of the meeting called for the same morning, and to decide what further action the Vestry should take consequent on the result of the above described meeting. The Chairman ruled the motion out of order, and Mr. M. H. Judge then said he would call the attention of the Board of Trade to the irregularity of the morning's proceedings. A further complication is possible, owing to the fact that the resolution passed does not specifically refer to the Provisional Order as amended by the Vestry, and the one actually before the Board of Trade differs in several respects from that agreed to by the Vestry.

The Birmingham Exhibition.—The committee of this Exhibition have sent a cheque for £101. 7s. 2d. to each of the three Birmingham hospitals, to which the surplus of the receipts of the Exhibition was to be given. The closing of the accounts was prevented, it is stated, by a threatened lawsuit involving a large sum of money. As soon, however, as an arrangement was come to the committee were able to deal with the balance of the funds. The accounts have been audited by a chartered accountant, but on the ground of expense it is not intended to publish them; though, if desired, they can be seen with all the accompanying papers at the office of the Secretary, Mr. T. C. Sharp. The following figures were, however, supplied to the *Birmingham Daily Post* by Mr. Sharp:—The total receipts were £12,059. 14s. 5d. The particulars of the expenditure are: Fitting up hall, £3,856; rent and insurance, £769; bill-posting, £1,815; band and entertainments, £1,300; coal and water, £272; law expenses (including £55 10s. paid to settle the claim), £255. 10s.; medals, £75. 10s. These items, with the £304 divided among the hospitals, make up a total of £8,647. There is thus a balance of £4,412, which is accounted for by salaries, wages, royalties, bank charges, professional charges, travelling expenses, carriage, and other items, of which the details are not given.

The Laurent-Cely Accumulator.—The special features of the Laurent-Cely accumulator, which is constructed by the Société Anonyme pour le Travail Électrique des Métaux, consists, says *Engineering*, in the special nature of the lead paste employed, and in the manner in which it is applied to the plates. The active element is a mixture of chloride of lead and chloride of zinc. The fused chloride of lead has a density of 5·6; by incorporating chloride of zinc with it in certain proportions the density is reduced to 4·5. This mixture, brought to a state of fusion, is run into cast-iron moulds in the form of small buttons with rounded edges. After cooling, the buttons are washed to remove the chloride of zinc, and thus to render them somewhat porous. Their density then varies from 4·2 to 3·4. The buttons which serve for the manufacture of the negative plates are then arranged in a metallic mould, into which antimonial lead is run; this surrounds the buttons with a frame which holds them fixed in their positions. The negative plates are mounted in cells filled with acidulated water and provided with zinc electrodes. The composite and zinc plates are then short-circuited. The hydrogen which is disengaged upon the positive electrode reduces the chloride of lead, and there are thus obtained buttons of spongy lead of a density between 2·5 and 3·1, while that of ordinary lead is 11·35. The buttons used in the manufacture of the positive plates are first transformed into spongy lead, then heated in the air to oxidise them, and transformed into spongy litharge. They are fixed, like the negative buttons, in a frame of antimonial lead. The Laurent-Cely accumulator is employed for the lighting of the *wagons lits* on the Chemin de Fer du Nord, and has also served to drive a motor working an electric capstan.

Electricity Behind the Stage.—In a recent issue of the *Electrical World* there is an interesting account of the manner in which electricity is called into play to produce a realistic representation of a horse race in "The Country Fair" at the Union Square Theatre, New York. The electric lights are flashed out, and after a few moments of darkness the flying horses appear at the back of the stage in a blaze of light. They seem to be straining every nerve, and flying past a varied landscape. Fences and trees disappear behind them with startling rapidity, and when at last the finish is near one of the horses gradually works forward, winner by a neck as he approaches the judges' stand; then an instant of darkness, and in the flash of light that follows the horses are pulled up beyond the stand, and the race is won. The picket fence behind which the horses appear to be running, and the varied scenery that is beyond, are both set in motion by the judicious application of the electric motor. Both fence and scenery form endless belts, which move at the same speed past the horses, producing the effect of rapid motion of the animals in a contrary direction. The fence in the foreground runs over flanged wheels specially adapted for the purpose, and has guides that hold it rigidly perpendicular during its passage over the stage. As the race nears the finish, the platform on which the winning horse is stationed is gradually slipped forward on a track provided for the purpose until the finish, the actual movement being, of course, only a few feet. The space between the fence and the scenery behind is 14ft., giving ample room for free action of the horses. Much of the effect of the scene is due to the extreme suddenness with which the electric lights can be flashed off and on, throwing the stage from extreme darkness to brilliant light and back again in an instant, so that the whole scene appears as a vivid panorama before the audience. A switchboard on the left of the stage enables one man to control the lights and the mechanism by which the scene is given, and this is in part the reason why electricity has been used so freely. It is proposed to still further increase the application of motors at this theatre, and so to arrange things that, as far as possible, all mechanical devices and moveable scenery will be handled by motors from one point with great rapidity, and without the danger of trouble from careless attendants.

MAGNETISM IN IRON AND OTHER METALS.*—XIX.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 58.*)

§ 79. Dissipation of Energy through Magnetic Hysteresis.—One very important consequence of magnetic hysteresis is that changes of magnetisation (on the part of iron and the other magnetic metals, all of which exhibit hysteresis) involve a dissipation of energy. When the magnetism is carried through a cyclic series of values, the curves showing the relation of I to H form a loop, and the area of that loop, in other words, the integral $\int \mathsf{H}\, d\,\mathsf{I}$, measures the amount of energy dissipated during the cycle through hysteresis.†

Perhaps the simplest way to prove this is to think of the magnetisation as being produced by a current in a magnetising solenoid, and to consider the work done by the current when the magnetism changes. To fix the ideas, take as the core of the solenoid a ring or very long rod, of length l and cross-section s, wound with a solenoid of n turns per centimetre, so that the whole number of turns is ln. Say that its magnetic induction is increased by an indefinitely small amount, $d\,\mathsf{B}$, in an indefinitely small time, dt, by increasing the magnetising current to an indefinitely small extent. Then the whole number of lines of induction within the solenoid is increased by the number $s\,d\,\mathsf{B}$, and the time-rate of this increase is $s\frac{d\,\mathsf{B}}{dt}$. This induces in the surrounding solenoid an electromotive force equal to $l\,n\,s\frac{d\,\mathsf{B}}{dt}$ in the direction opposite to that of the current. The current has accordingly to do work in overcoming this opposing electromotive force, over and above whatever further quantity of energy it expends in heating the conducting wire. With this last source of loss we need not concern ourselves: we wish to find the energy which is spent in producing magnetisation. Let C be the mean value which the current has during the time dt. The opposing electromotive force, due to the change of magnetic induction in the core, when multiplied by the current and by the time dt, gives the quantity of work done by the current. Hence the work done by the current in producing the change of magnetism $d\,\mathsf{B}$ is

$$l\,n\,s\frac{d\,\mathsf{B}}{dt}\,\mathrm{C}\,dt, \text{ or } l\,n\,s\,\mathrm{C}\,d\,\mathsf{B}.$$

The fact that dt disappears shows that this work does not depend on the time-rate at which the change of induction takes place; we have the same quantity of energy used in the process whether the change $d\,\mathsf{B}$ takes place fast or slowly. Since the volume of the core is ls, we may write $d\,\mathrm{W}$, the work done by the magnetising current per unit of volume (that is, per cubic centimetre), in bringing about the change $d\,\mathsf{B}$, as

$$n\,\mathrm{C}\,d\,\mathsf{B}.$$

But the magnetising force H is $4\pi\,\mathrm{C}\,n$, hence

$$n\,\mathrm{C} = \frac{\mathsf{H}}{4\pi}, \text{ and } d\,\mathrm{W} = \frac{1}{4\pi}\,\mathsf{H}\,d\,\mathsf{B}.$$

To obtain the work done per cubic centimetre of the metal when B is changed by any finite amount by changing the magnetising force from (say) a value H_1 to another value H_2 we have to integrate this expression, finding

$$\mathrm{W} = \frac{1}{4\pi}\int \mathsf{H}\,d\,\mathsf{B}$$

between the limits H_2 and H_1.

Thus, in Fig. 46, if P and Q are any two points in the curve of B and H, the work done per cubic centimetre as the magnetic state alters from P to Q is the area M P Q N divided by 4π. For example, in magnetising a piece which has no magnetism to begin with, the curve followed being O P (Fig. 47), the work done in reaching P is equal to the area O P M divided by 4π. If we then remove the magnetising force (curve P R) we *recover* a quantity of work equal to the area R P M, divided by 4π; the net expenditure of energy in the whole process is, therefore, equal to the shaded area O P R, divided by 4π.

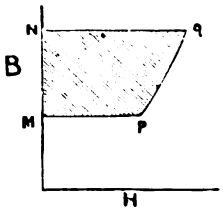

Fig. 46.

In this case the final state of the metal at R is different from its initial state at O, and it is therefore not immediately obvious how much of this energy has been spent irrecoverably. But let a *cyclic* process be followed, so that at the end the magnetisation, as well as the magnetising force, is brought back to the value it had at the beginning; in that case there can be no accumulation of recoverable energy at the end of the cycle.

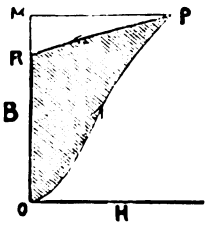

Fig. 47.

The whole difference between what is spent during one part of the process and what is recovered during the other part is therefore *dissipated*, and simply goes to heat the metal. Thus, when we carry the metal through cyclic magnetic changes such as are represented in Fig. 48, where the magnetising force is removed and reapplied, or in Fig. 49, where it is reversed and

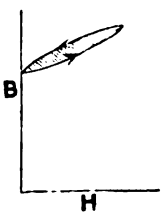

Fig. 48.

re-reversed, there is a quantity of energy dissipated in each cycle per cubic centimetre of the metal equal to $\frac{1}{4\pi}\int \mathsf{H}\,d\,\mathsf{B}$; in other words, it is equal to the shaded area enclosed by the curves connecting H and B, divided by 4π.

Moreover, since $d\,\mathsf{B} = 4\pi\,d\,\mathsf{I} + d\,\mathsf{H}$,

$$\frac{1}{4\pi}\int \mathsf{H}\,d\,\mathsf{B} = \int \mathsf{H}\,d\,\mathsf{I} + \frac{1}{4\pi}\int \mathsf{H}\,d\,\mathsf{H}.$$

But in a cyclic process, $\int \mathsf{H}\,d\,\mathsf{H}$ vanishes; and the energy dissipated in a cycle is, therefore,

$$\int \mathsf{H}\,d\,\mathsf{I}.$$

Thus in Figs. 48 and 49, if we represent the magnetism by I instead of by B, the shaded area measures the amount of energy dissipated in each cubic centimetre of the magnetised metal during the cyclic process which the curves represent.

* All rights are reserved.

† This was first shown by Warburg in an important paper dealing with several effects of magnetic hysteresis, *Wied. Ann.*, XIII. (1881), p. 141. He proved it by supposing the magnetic force to depend upon the position of permanent magnets, and calculated the work spent in carrying these magnets through the necessary cyclic changes of position. It was afterwards discovered independently by the writer, who showed that it could be readily deduced from Maxwell's general equations of the electromagnetic field (*Proc. Roy. Soc.*, May, 1882, No. 220, p. 39; *Phil. Trans.* 1885, p. 549). The method of proof followed in the text is substantially Hopkinson's, *Phil. Trans.*, 1885, p. 456; see also Lord Rayleigh, *Phil. Mag.*, Vol. XXII., p. 176.

As C.-G.-S. units are used in expressing H and I, the area within the curves gives the energy dissipated (per cubic centimetre) in C.-G.-S. units of work, or ergs.

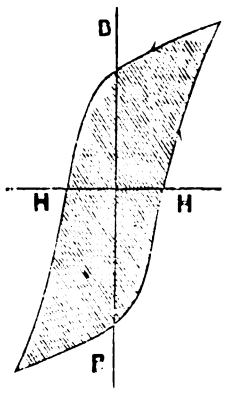

Fig. 49.

§ 80. **Heating Effect of a Cyclic Process.**—The dissipated energy takes the form of heat: hence iron and other metals in which there is magnetic hysteresis become warmed when their magnetism is successively reversed or varied in any way—the effect of reversal being much more marked than the effect of simple removal and reapplication of a magnetising force, because of the much greater area of the reversal loops.

The iron of transformers and the cores of dynamo-armatures are familiar instances in point. The heating which occurs as a consequence of hysteresis has, of course, nothing to do with the additional heating which Foucault or eddy currents may cause when quick changes of magnetism are made to take place in iron which is not sufficiently laminated. Hysteresis causes heating however slowly the magnetism changes, and however minute are the subdivisions of the core.

To find the rise of temperature which a magnetic metal suffers when its magnetism is cyclically varied, we have to reduce the value of $\int \mathsf{H}\, d\,\mathsf{I}$ to thermal units, and divide by the number of grammes in a cubic centimetre, and by the specific heat. Using centigrade degrees, there are 41,600,000 ergs in a thermal unit. In iron, the specific heat is 0·11, and there are 7·7 grammes in a cubic centimetre. Hence, the rise of temperature caused by a magnetic cycle is—

$$\frac{\int \mathsf{H}\, d\,\mathsf{I}}{41{,}600{,}000 \times 7{\cdot}7 \times 0{\cdot}11} = 2{\cdot}84 \times 10^{-8} \times \int \mathsf{H}\, d\,\mathsf{I}.$$

§ 81. **Values of $\int \mathsf{H}\, d\,\mathsf{I}$.**—In soft annealed iron the value of $\int \mathsf{H}\, d\,\mathsf{I}$, for each double reversal of a condition of strong magnetization is about 10,000 ergs. Nearly 4,000 double reversals would therefore be necessary to raise the temperature of a soft iron core by 1° C., if the influence of eddy currents could be excluded.

Since there are 7·7 grammes of iron in 1 cubic centimetre, and 453·6 × 2240 grammes in a ton, the energy dissipated in taking one ton iron through a magnetic cycle is

$$\frac{453{\cdot}6 \times 2240 \times \int \mathsf{H}\, d\,\mathsf{I}}{7{\cdot}7}.$$

Suppose that there are n cycles per second: the work done in ergs per second is then

$$\frac{n \times 453{\cdot}6 \times 2240 \times \int \mathsf{H}\, d\,\mathsf{I}}{7{\cdot}7}.$$

We may reduce this to horse-power by dividing by $7{\cdot}46 \times 10^9$, which is the number of ergs per second in 1 horse-power. Hence the horse-power consumed through magnetic hysteresis when one ton of iron is taken repeatedly through a set of cyclic changes of magnetism at the rate of n cycles per second is

$$0{\cdot}00001769\, n \int \mathsf{H}\, d\,\mathsf{I}$$

Applying this to the case of soft annealed iron, where $\int \mathsf{H}\, d\,\mathsf{I}$ for double reversals of strong magnetisation is about 10,000 C.-G.-S. units, the horse-power per ton, for 100 cycles of double reversal per second, is 17·7.

In harder specimens of annealed wrought-iron the value of $\int \mathsf{H}\, d\,\mathsf{I}$ for a double reversal of strong magnetism may be as much as 16,000. Hardening by mechanical strain increases the area within the curves, as a reference to Figs. 34 and 38 will show. In mild steel Hopkinson's experiments * show that the value ranges from that found in wrought iron up to 40,000 or even 60,000; it increases in a general way with increase in the percentage of carbon, and is greater in specimens which are hardened by quenching than in those which have a lower temper. In high carbon steels the value may exceed 60,000. In pianoforte steel wire 94,000 has been obtained when the metal was annealed, 116,000 when in its commercial state, and 117,000 when hardened by quenching in water from a red heat. Chrome steel (containing about 1 per cent. of chromium) ranged from about 65,000 (annealed) to 167,000 (oil-hardened). In tungsten steel Hopkinson found even higher values; an oil-hardened French specimen containing 3·4 per cent. of tungsten, 0·5 per cent. of carbon, and 0·6 per cent. of manganese, consumed 216,800 ergs, or more than twenty times the amount consumed in soft wrought-iron. The dissipation of energy in a cycle of double reversal is roughly equal to twice the coercive force multiplied by I.

In cast-iron, values of 30,000 to 40,000 appear to be usual; but in one sample of soft grey cast-iron Hopkinson has found so low a value as 13,000. In nickel, a hard-drawn wire gave 25,000, which was reduced to 11,000 when the wire was annealed. Thus the dissipation of energy in nickel when a strong magnetising force is reversed is much the same as that in wrought-iron, the greater coercive force of nickel being counterbalanced by the lower intensity of magnetism it is capable of reaching, even when "saturated."

(To be continued.)

THE CHELSEA ELECTRICITY SUPPLY COMPANY'S STATION AND SUB-STATIONS.

The system of distribution adopted by the Chelsea Electricity Supply Company, in which storage batteries are provided of sufficient capacity to supply the whole demand for current, is worthy of careful study and attention; because, although somewhat complicated at first sight, it is free from the objections which have been so strongly urged against other systems. The continuity of the supply is not dependent upon moving machinery; efficient motors of low cost can be readily employed; the high-tension charging current is not brought near the consumer's premises; continuous service is secured without the necessity for a double staff of attendants, or for running steam plant with uneconomical loads.

We propose now to give a general description of the system adopted by the Chelsea Company, and of their station at Draycott Place and sub-stations in connection with it. Those of our readers who wish to examine into the details of the arrangements and connections are referred to the Paper by Major-General Webber, read before the British Association last year, and reprinted in our columns (*The Electrician*, October 11 and 18, 1889), where diagrams of connections, &c., will be found.

The system consists essentially in the establishment of a number of substations, which are distributed over the area of supply, each furnished with a large storage battery, which is divided into two parts, so that one part may be charged while the other part is feeding the distributing network. At the time of greatest demand both halves of the battery are coupled up in parallel with each other to the distributing network. When being charged the half-battery at each sub-station has its cells coupled in series throughout, and the several substations are also connected in series by the charging cable, so that a high-tension current is employed to effect the charging.

* *Phil. Trans.*, 1885, p. 463.

Digitized by Google

The discharging halves of the batteries have their cells coupled in sets of 55 for 100-volt circuit, which are then coupled in parallel to the distributing network. Continuous-current transformers are to be put down at each sub-station, and at the time of our visit the first of these was being arranged for testing. In some tests which have already been made with this machine the efficiency was 75 to 80 per cent. The transformers absorb the full power of the engines and dynamos, and are intended to be coupled to the distributing feeders, parallel with the batteries, at the time of maximum demand during the winter months; they will be regulated so as to work at full load—that is, their E.M.F. will be slightly higher than that given by the batteries, the object of which is to avoid running the engines with light loads, and to maintain the batteries as fully charged as possible. It was stated at the meeting of the Chelsea Company in February last that the coal consumption per Board of Trade unit delivered to the customers was, on the average, about 11lb., which is a much lower figure than that recorded with any other system of supply, and which may be accounted for by the fact that the plant is never running except on full load.

One of the features of the system is that the number of charging dynamos in operation always equals the number of half-batteries being charged. The dynamos and half-batteries are connected all in series, and when a battery becomes fully charged and is cut out of the charging circuit the corresponding dynamo is stopped at the generating station. This will be effected automatically eventually; but at present it is done by the attendant, who sees by his voltmeter and ammeter the moment when a battery is cut out of circuit.

The number of charging dynamos already fixed is five, four in operation (that being the number of sub-stations) and one spare. The dynamos are mounted on the same bedplate and coupled direct to Willans compound engines of G.G. type. Raworth's flexible couplings are employed, and the dynamo spindle is insulated from the engine by the interposition of an ebonite disc and collars. The dynamos are of the Victoria type, giving an E.M.F. at their terminals of about 530 volts and 75 amperes, at a speed of 424 revolutions per minute. The field-magnets of the charging dynamos are excited from a separate dynamo driven by a small engine. The exciting dynamo is compound-wound for constant difference of potential, so that no variation is caused by switching off the magnets of one or more of the charging dynamos. The armatures of the charging dynamos are coupled in series as before explained. A variable resistance is provided in connection with the field coils of each, so that the E.M.F. can be adjusted independently on all the dynamos. When both halves of a battery become fully charged, and are consequently cut out of the circuit, the exciting circuit of a dynamo is broken, and the armature afterwards short-circuited. For a moment, then, the charging current flows through the inactive armature; but it will be seen that this has no objectionable result. The switches which control the exciting and armature circuits of each dynamo are ranged side by side; and a star wheel placed between them prevents the possibility of the armature being short-circuited before the exciting current has been broken, or the exciting current being put on before the armature has been thrown into the charging circuit.

In order to avoid a back current flowing from the batteries through the armatures of the charging machines consequent on any mistake on the part of the attendant, or a mishap, such as the sudden stoppage of the exciting current, a gravity switch, which breaks circuit if the current falls below a minimum value, is inserted in each of the charging leads; and to avoid disastrous consequences, should these fail to act in event of a sudden reversal of the current, a safety device is introduced (Fig. 1). It consists of a magnetic cut-out, set to act at 80 amperes, which is connected in the charging circuit; a fuse wire, which supports the heavy copper switch bar, is connected in parallel circuit with the magnetic cut-out. If the current rises above 80 amperes, the cut-out operates, leaving the fuse wire in circuit; this is immediately melted, in consequence of which the heavy copper switch bar falls, breaking both charging and exciter circuits.

The four sub-stations now in operation are situated at Draycott-place, Clabon-mews, Egerton-mews, and Pavilion-road. The last-named is just being started. Each sub-station contains 454 E.P.S. cells of the size known as 31L, *i.e.*, 440 for supplying the lamps and 14 back E.M.F. cells. Each cell stands on a separate wood tray, which again rests on oil insulators. A light traveller is fitted up in each battery room, with the help of which any of the cells can be removed for inspection or repair. The Clabon-mews sub-station consists of two battery rooms, 13ft. 6in. by 10ft. 4in. and 30f . by 9ft., and the cells are arranged five tiers high on the walls and on a central framework. The switch-room, which contains all the automatic transposing and regulating apparatus, is 8ft. 4in. by 8ft. Each battery-room is ventilated by a Blackman air propeller, coupled direct to a motor, which is placed in an opening made in the wall. The switch-room of a sub-station contains a number of automatic appliances, which, though appearing at first sight to form a very complex arrangement, becomes quite clear and simple when the function of each piece of apparatus and its relation to the whole is understood.

Upon commencing the day's charging the attendant at the generating station turns on a small switch for each sub-station, after which he switches the charging dynamos into circuit. Each small switch controls a relay at the sub-station connected with the operating magnet of a large transposing switch (Fig. 2) which is provided for each half battery. The function of the transposing switch is to connect the cells of the

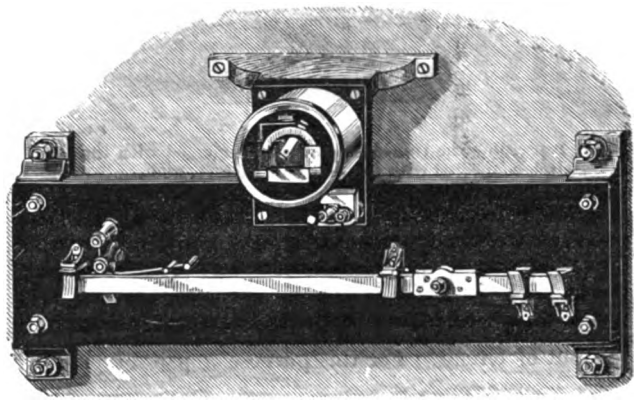

Fig. 1.—Safety Cut-out.

half battery either in series and to the charging main, or in parallel and to the distributing feeders, which it does by means of a number of contacts which are mounted on a rocking framework. When the rocking frame is down on one side, the set of contacts on that side dip into the set of mercury cups and connect the battery in series for charging; and when it is down on the other side the other set of contacts dip into the other set of mercury cups, and connect the battery in parallel for discharging. Suppose, then, that the attendant at the generating station has turned on the switch which sets the automatic apparatus in operation, the transposing switch of the first half battery is thereby thrown over from discharging to charging side, and the charging proceeds. In order to automatically cut the battery out of the charging circuit as soon as it is fully charged, a single negative plate in the half battery is selected, and a cap is arranged to catch the gas given off by the plate. The gas is led through a bubbling bottle into a small gasometer, which is adjusted so as to make a contact when the cells are properly charged, which operates a magnet on the transposing switch, causing it to rock over, and connect the cells in parallel on to the distributing feeders. The movement of this transposing switch makes a contact which causes the transposing switch of the second half-battery to rock over from the discharging to the charging position, and the charging goes on until the gasometer, which in the meantime has been emptied by an electrically operated valve, has again risen high enough to make contact, when the second half battery is disconnected from the charging mains and thrown on to the distributing feeders parallel with the

Digitized by Google

first half. To prevent the charging circuit being broken a carbon resistance is automatically connected across the terminals of the charging mains before the charged half of the battery is disconnected, and remains connected until the second half of the battery is connected in for charging.

carrying four contacts. When the E.M.F. is normal the cross arm remains in a central position between four other contacts. If the cross arm is pushed upwards consequent on an increase in the E.M.F., the top contacts on the cross arm close a relay circuit, which operates a step by-step device (Fig. 4), which at each

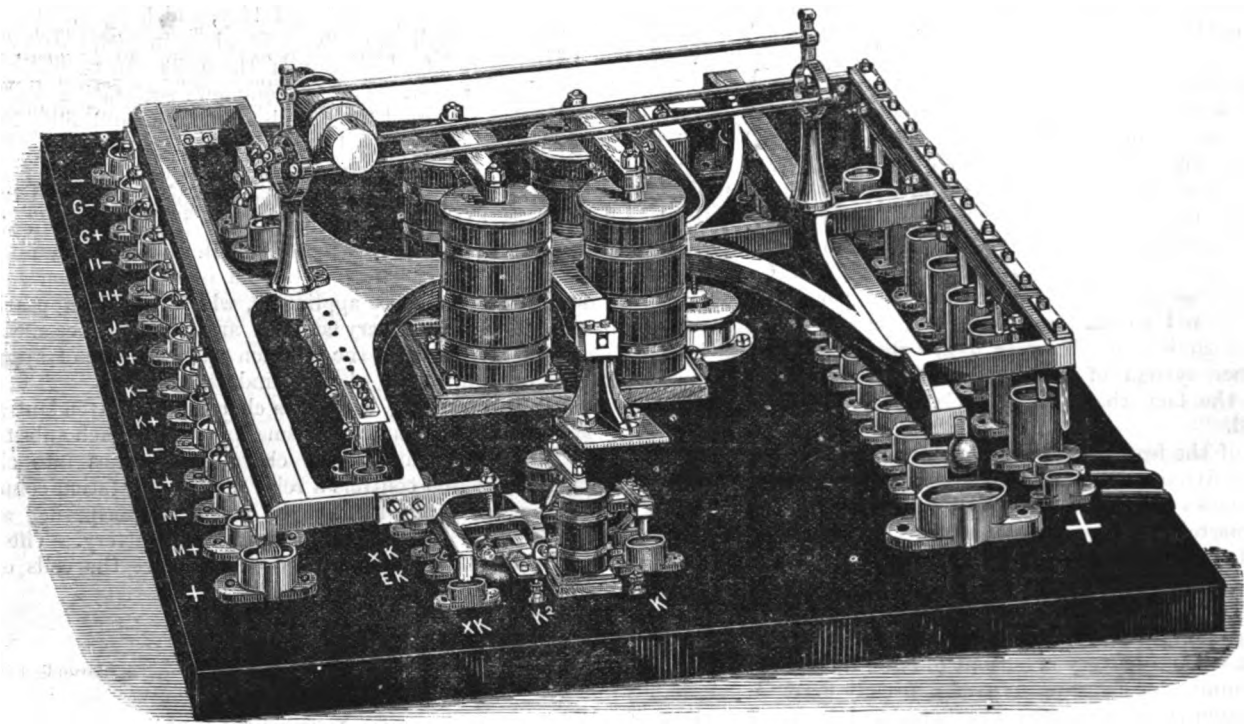

FIG. 2.—Transposing Switch.

This figure represents the transposing switch connected with the second half of a sub station battery. The small relay is actuated by the transposing switch connected with the first half battery, and controls the main magnet, which pulls the rocking frame over to the "charging" side.

The regulation of the E.M.F. delivered to the distributing feeders is performed as follows by means of counter E.M.F. cells. By this arrangement the whole of the cells are uniformly discharged, a condition essential to the maintenance of the battery in good order. These regulating cells are automatically switched in and out of circuit. For this purpose a pair of pilot wires

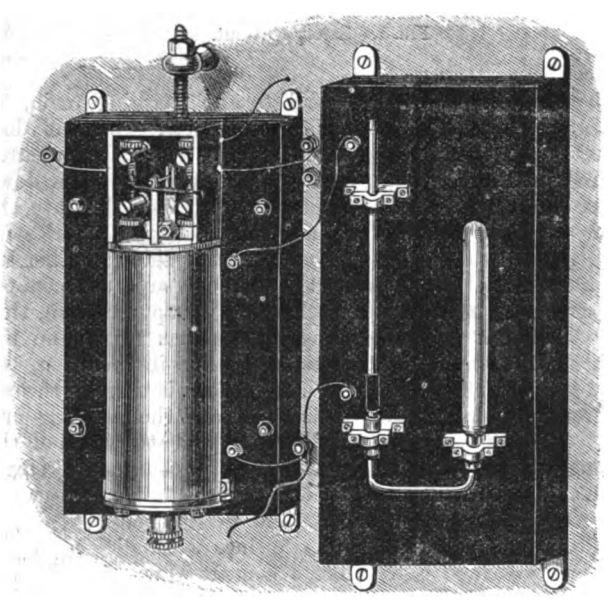

FIG. 3.—E.M.F. Governor.

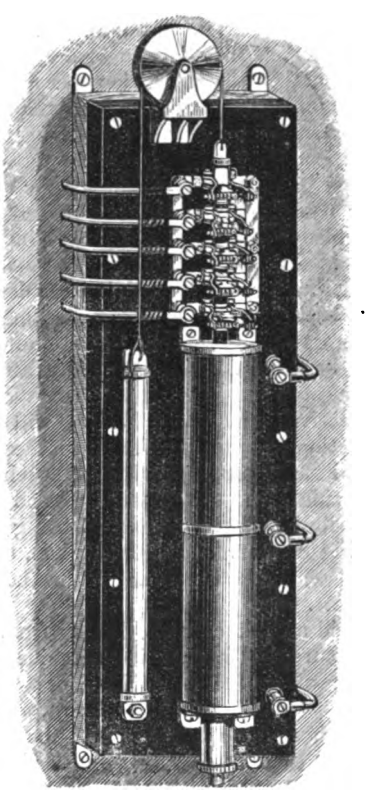

FIG. 4.—Step-by-step Device connected with E.M.F. Governor.

are brought from the point on the network where it is desired to maintain a constant E.M F. These pilot wires are connected at the substation to the terminals of a governor (Fig. 3), which consists of a high resistance solenoid—ingeniously compensated for temperature variations—with a balanced core, to the top of which is attached a cross arm,

step causes a back E.M.F. cell to be introduced into the circuit, through the intervention of the mercury switch (Fig. 4A).

When a sufficient number of cells has been introduced the core moves down, breaking the contact, and the action ceases. Similarly, if the E.M.F. on the network falls, the core of the governor descends, the cross arm makes another pair of

Digitized by Google

contacts, and the reverse action of cutting out back E.M.F. cells takes place. The solenoid of the governor, through which the current from the pilot wires passes, is compensated against the effect of the surrounding temperature, which would otherwise cause considerable variation in the voltage maintained on the network. Instead of both ends of the operating solenoid being connected directly to the pilot wires, one end is connected through a carbon rod about $\frac{1}{32}$nd inch diameter, which introduces resistance. This carbon rod passes down the centre of a small glass tube, which is partly filled with mercury. The mercury is in connection with a closed chamber filled with alcohol, the expansion and contraction of which when the temperature of the room varies causes the mercury to rise or fall in the tube and to short-circuit more or less of the carbon rod.

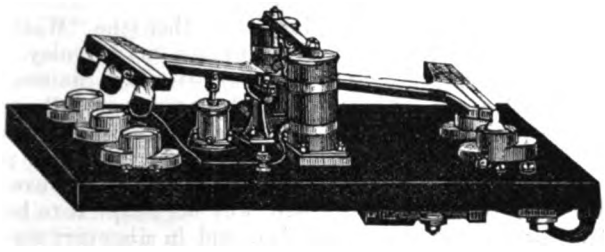

FIG. 4A.—Mercury Switch connected with the Step-by-step Device.

This device is adjusted to keep the total resistance always the same, and thus compensate for variations of temperature.

If the difference between the currents delivered by the two halves of the battery exceeds 10 per cent. of the whole, back

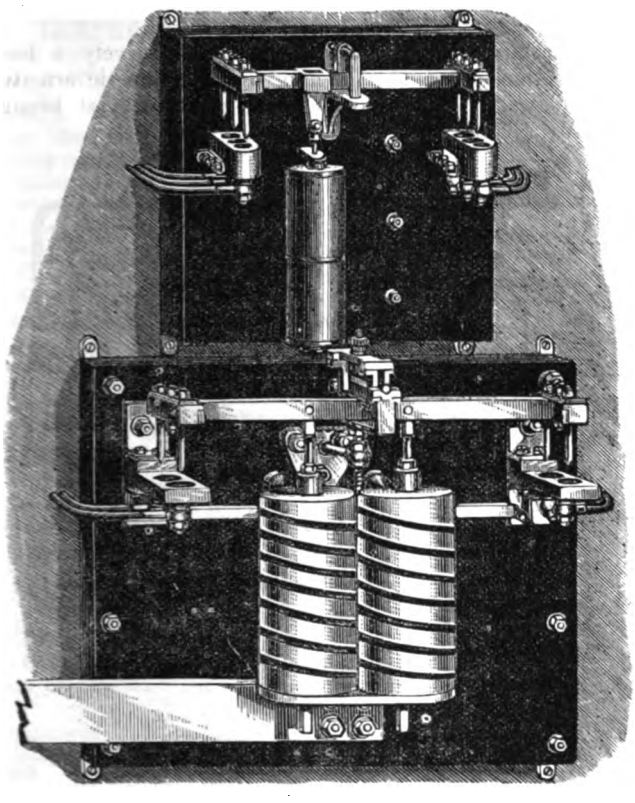

FIG. 5.—Current Regulator and Relay. The relay here shown is the one actuated either by the current regulator or the E.M.F. governor, as the case may be, and sends the currents which actuate the step-by-step device (Fig. 4)

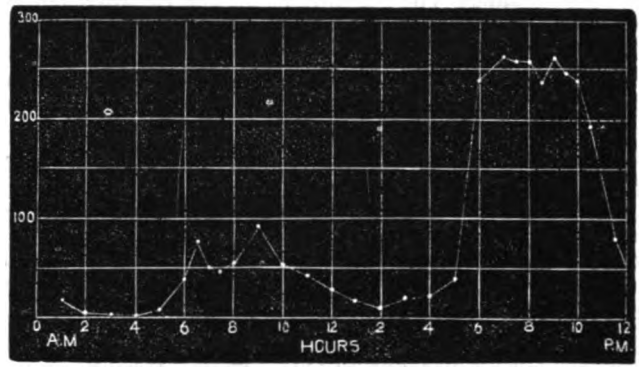
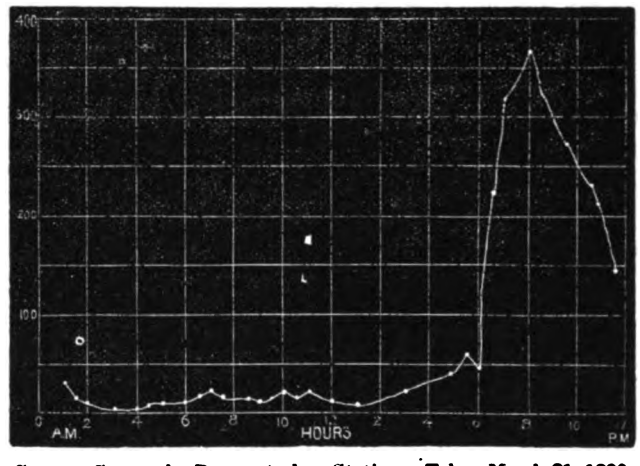
E.M.F. cells are introduced into one-half, or cut out of the other through the intervention of the current regulator (Fig. 5), which consists of two solenoids formed by cutting a spiral out of a piece of copper tube. The spirals are placed side by side, and the current from each half of the battery passes through them. The solenoids pull down either one side or the other of a balanced contact arm, which causes, through the medium of the relay (Fig. 5) and the step-by-step device (Fig. 4), a back E.M.F. cell to be switched out of the half-battery which is not supplying its share of current.

A large main switch and ammeter for the discharge circuit and an ammeter for the charging circuit is provided, and also a smaller ammeter having flexible leads and a wedge contact, which when forced between the proper contact plates diverts the current from any group of 55 cells through the ammeter, so that the current delivered by each group can be measured at will. Nothing can be easier than to keep a perfectly safe insulation between the charging circuit and the distributing network now—a good stretch of enamelled slate separating the contacts in the switch-room. We would suggest that every possible precaution should be taken to prevent this satisfactory state of things being impaired by the introduction of the continuous-current transformers.



Current Curve, the Clabon-mews Station. Taken March 4, 1890.

The present capacity of the station and sub-stations is about 10,000 lights; but the ultimate capacity, reckoning the continuous-current transformers, will reach 30,000 8—10 candle-power lamps. The Company find that 8—10 candle-power lamps give very satisfactory lighting, and that if 16 candle-power lamps are put in, the customer complains of the bill at the end of the quarter. The houses supplied by the Chelsea Company average about 100 lights (wired), in each of which the average maximum number burning at one time is about 35. Thus, each sub-station is able to supply about 70 houses.



Current Curve, the Draycott place Station. Taken March 21, 1890.

Taking the number of houses likely to take the light as about 1 in 4 (which is quite high enough), the ultimate number of sub-stations being 10, we get $70 \times 4 \times 10 = 2{,}800$ houses, which gives a rough idea of the area over which the Chelsea Company's supply from Draycott-place will extend. The charge is made by meter—the Aron being generally employed. The price charged is 8d. per unit, though the Company are empowered by their Act to charge 10d. per unit. A charge of 5s., 7s. 6d., or 10s. per quarter, according to size, is made for rent of meter.

The mains are laid underground on the Callender-Webber system, which has gained great favour with the Company's

Digitized by Google

engineers. Their experience shows that when a separate channel is provided for each cable, as is the case in this system, long lengths of heavy cable can easily be drawn in or out. A 91/12 cable, 2in. in external diameter, 400 yards long, was recently drawn into a channel 2⅜in. diameter without difficulty, the cable being drawn 200 yards each way from a central opening. Thirteen men were employed in pulling the cable in. If a separate iron pipe were employed for each cable the cost would be too great; and experience has shown that even if a large pipe is used the cables drag very heavily one on another if several are drawn into the same pipe. As regards the relative values of rubber or gutta percha and bitumen, it is believed that the superiority of the former is seldom utilised to the full, as underground cables fail either through mechanical damage or the attacks of deleterious gases or liquids, to which rubber and gutta percha are equally as susceptible as bitumen. The charging mains (19/14) are about two miles in length, and the charging E.M F. reaches 2,200 volts.

The boilers are of the Babcock and Wilcox type of 100 horse-power nominal. There are two of these already fixed, and space is provided in the boiler-house for two more. The feed-water is supplied by a Worthington pump, and, in addition, injectors are fitted to each boiler in case of the pump failing from any cause.

The coal bunkers are situated opposite the boilers, and extend under the roadway, so that the coal is dumped where it is wanted in the first instance. The coal storage capacity is equal to about 80 hours consumption.

We give on the preceding page some supply curves taken from two of the sub-stations, a glance at which will show that the current consumed during the daytime—though it would result in a loss if it necessitated constant running of plant—yet bears no mean proportion to the whole supply, and might make all the difference between a good dividend and none at all.

THE THAMES ELECTRIC LAUNCH FLEET.

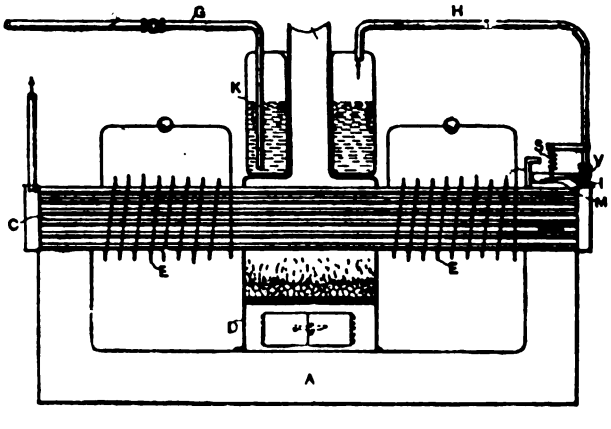
The small fleet of electric launches which figured so prominently on the Thames last season will, this year, receive several additions. Hitherto the number of this new type of river boat on the Thames has been about fourteen; this year there are to be two or three-and-twenty. Of the existing fleet far away the finest is the "Viscountess Bury," owned by Messrs. Immisch. Since she was first brought into prominence some important improvements have been made in this vessel. The first alteration was the addition of a certain amount of "dead-wood" under the stern to assist the steering properties of the launch. She also possesses now a greater length of saloon, and, by sundry other internal rearrangements, her saloon accommodation has been materially enlarged and improved. Over all she measures 70ft. by 10ft., and 60 or 70 people can be comfortably carried. She is now worked by a single motor and one 19in. propeller. When prepared for a trip she is fitted with 164 storage cells. The motor takes on the average 45 amperes and 164 volts. She is steered from the bow end of the upper deck, and, as a rule, runs at about seven miles an hour. The saloon is, of course, amply furnished with glow-lamps, and electric side-lights are provided. The "Ray Mead" is almost twin with the "Viscountess Bury," but is somewhat wider and shorter. The remainder of the present fleet,—all owned by and electrically fitted by Messrs. Immisch (or by the syndicate of which they are the visible embodiment)—are much smaller than these two. They average in length from 30ft. to 40ft., are worked by single motors with 17½in. propellers, and are provided with from 30 to 40 storage cells, giving an average current of 27 amperes. They are furnished with such electric lamps as may be necessary, but they are all open boats. Their travelling capacity is, however, pretty much the same as that of the larger launches, and they are much in favour for daylight trips.

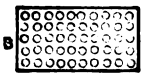
The new electric launches that are at present building for the Thames number something like eight. They are almost entirely for private owners, and will in all essential features resemble the smaller boats last described. They will probably be more luxuriously fitted, though they will not otherwise show an advance on the existing launches, but, as the electrical plant will come from the same source they will be equal in that respect. In addition to these new craft there is a small flat-bottomed electric launch being built at Hammersmith for Baron de Rothschild for use on the Dutch canals and on private waters.

Anyone who has travelled on or watched an electric launch gliding through the water can well appreciate the smoothness and quietness of its motion as compared with that of the puffing and rattling of the majority of steam launches, and of the malodorous naphtha launch. With respect to charging stations on the river there is little new to be said. It was expected that some additional shore stations would be erected, but the only one at present finished is that on Platt's Eyot; three others will be shortly equipped. Of the two largest floating stations, one is already at Maidenhead, the other (the "Watt") is now at the Eyot, but later on she will move up to Henley. The rest are, or will be, moored at Reading, Windsor, Staines, and other suitable spots. Kingston is perhaps too near to Hampton for the purpose, but it is suggested that a charging station might very well be moored at that busy and important boating place as a starting point. Seeing how well electricity has answered for launches, the question is raised, why not adapt it to house-boats, which are growing in numbers and in size every season? An electrical plant would be an immense advantage to these floating dwellings, and there would be much saving of steam and horse traction. It only remains for some ingenious mind to make the first experiment and show the way.

THE TESLA THERMO-MAGNETIC GENERATOR.

The accompanying engravings show respectively a longitudinal section and a cross section of the magnetic armature core employed in a thermo-magnetic generator just brought out by Mr. Nikola Tesla.





The Tesla Thermo-Magnetic Generator.

The generator, says the *Electrical Engineer* of New York, from which we take the account, is provided with a magnetised core or permanent magnet, A, the poles of which are bridged by an armature core composed of a shell B, enclosing a number of hollow iron tubes, C. Around this core are wound the conductors E E, forming the coils in which the currents are developed. D is a closed fire-box, and above the fire is a boiler, K, containing water. The latter is supplied by means of the pipe G, and the steam exhaust pipe H communicates with all the tubes C in the armature, so that steam escaping from the boiler will pass through these tubes. In the steam exhaust pipes is a valve, V, to which is connected the lever I, by the movement of which the valve is opened or closed. The lever

Digitized by Google

carries an armature, M, and is held up in position to close the valve V by means of a spring, S.

In its normal condition, the armature B is magnetic along its entire length, and closes the magnetic circuit of the magnet A. Very little external magnetism is therefore exhibited, and the attraction upon the armature M is insufficient to draw it down against the force of the spring S. The steam exhaust, in consequence, remains closed. When the temperature of the central part of core B has been raised to about from 900° to 1,000° C., the magnetic circuit of magnet A is broken, and, in consequence, the external magnetism of core B greatly increased. This attracts the armature M, and allows steam to pass through the tubes C of the core. This lowers the temperature of the surface of the tubes at once, and restores, to a corresponding degree, their magnetic condition, whereupon the armature M is retracted and the steam cut off. This operation is continued, effecting a successive heating and cooling of the core, with the result of making and breaking the magnetic circuit. This entails a corresponding movement of the magnetic lines with reference to the coils E E, in consequence of which currents are developed in them.

It will be noted that by the construction adopted the source of heat is enclosed and the portions of the iron which are heated are not exposed to the air. The armature which closes the magnetic circuit is made of very thin tubes, and by this means an enormous cooling surface can be obtained. Steam is used for cooling in preference to air, partly because it is easier obtainable under pressure than air, and again, because it is more effective in consequence of its partial dissociation for which a large amount of heat is required.

THE TEMPERATURE-COEFFICIENT OF THE SWAN LAMP.*

There have been up to the present but few experiments concerning the temperature-coefficients of incandescent lamps. The following results will, therefore, be of some interest.

In order to measure the resistances of lamps at widely different temperatures, a bath of linseed oil was employed. The lamp to be tested was fastened to a stirrer (to which either a to-and-fro or up-and-down motion could be imparted) inside a glass bowl filled with oil. This bowl was suspended inside an enamelled saucepan filled with oil, and was also furnished with a stirrer. As soon as the oil reached the boiling point the saucepan was placed in a box of sawdust, and the resistance measured from time to time whilst the cooling took place. A nitrogen thermometer was used to take the temperature of incandescence of the lamp. The establishment of a contact between the lamp and the wires connected with the measuring apparatus presented considerable difficulties. As tin fuses at the temperatures employed, it was only possible to make use of lamps provided with platinum hooks. The contact of the latter with the copper wires was secured by means of an electrolytic deposition of copper.

The measurements were also somewhat difficult to effect, for the resistance of the lamp was not constant. This was caused by the heating of the filaments by the measuring current, although the latter was due to one Leclanché cell, and was, therefore, very feeble. This difficulty was overcome by inserting a high resistance in the battery circuit. The results thus obtained are given in the following tables :—

I.

Temperature of the lamp.	Resistance in ohms.	Temperature of the lamp.	Resistance in ohms.
300	51·003	175	54·982
273	51·826	137·5	56·174
245	52·688	22·5	59·492
209	53·834	20·0	59·560

II.

286·2	100·1	114·5	125·34
284·5	100·19	113	125·54
282	100·6	112	125·75
254	104·7	70·2	131·85
251·5	105·05	68·6	132·05
250·5	105·15	68	135·25
210	111·15	47·5	135·25
209	111·35	46	139·14
208·5	111·4	20·6	139·24
165	117·8	20·1	139·34
164	117·94	19·6	—
163	114·4		

* From *La Lumière Électrique*.

On plotting these results on squared paper it is found that they are fairly accurately represented by the formula

$$y = a + b\,x.$$

The temperature coefficient corresponding to the resistance at 20 deg. is

0·000513 for I.

and

0·001056 for II.

The two lamps were apparently of English manufacture.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, May 30th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Astronomical Telescopes." By A. A. COMMON, F.R.S.

SATURDAY, MAY 31st.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Ballad Music of the West of England." By the Rev. S. BARING-GOULD, M.A.

5 p.m. General Monthly Meeting.

MONDAY, June 2nd.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting. Paper to be read: "Pick's System of Manufacturing Salt in Vacuo." By PERRY F. NURSEY.

TUESDAY, June 3rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Natural History of Society." By ANDREW LANG.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Annual General Meeting.

THURSDAY, June 5th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Flame and Explosives." By Prof. DEWAR, F.R.S.

CHEMICAL SOCIETY.

8 p.m. "Note on the Preparation of Pure Crystalline Copper." By C. C. DUNCAN.

FRIDAY, June 6th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1). "The Effect of Change of Temperature on the Villari Critical Point of Iron." By HERBERT TOMLINSON, F.R.S. (2). "The Diurnal Variation of the Magnet at Kew." By W. G. ROBSON and S. W. J. SMITH.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Search for Coal in the South of England." By Prof. W. BOYD DAWKINS, F.R.S.

SATURDAY, June 7th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Ballad Music of the West of England." By the Rev. S. BARING-GOULD, M.A.

*** **Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.**

A Dynamo Telegraph Plant.—The dynamo plant of the Western Union Company, at Albany, N.Y., which has been in operation since July, 1889, displacing 7,000 Calland cells, has, says the *Electrical World*, greatly improved the service. The plant, which is located in the Edison Light Station, two blocks distant from the telegraph office, consists of nine Edison dynamos. Three potentials, 90, 150, and 250 volts, are found to be sufficient for all the service. Artificial resistance is added to the city wires and loops and other short wires, so that the 90-volt current can be used with perfect success. The currents are carried to the telegraph office in an aerial cable. There is also a spare cable between the station and the office on an entirely different route. An independent plant has been installed at an intermediate point on the route of the spare cable, for use in case of serious accident or interruption at the regular station. The independent plant consists of two dynamos, generating current at a potential of 250 volts. This is used to replace the highest potential sent out from the regular station, and supplies the quadruplexes. By means of rheostats, this current is cut down to meet the requirements of the other circuits.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

THE ELECTRICAL STANDARDISING LABORATORY.

The concluding paragraphs of Major CARDEW'S Paper, read recently before the Institution of Electrical Engineers, dealt with a matter of very practical importance, and brings a conception into the arena of realized ideals which was five years ago first presented in the same place in a Paper read before the Institution. On November 26, 1885, Dr. FLEMING laid before the members of that body his reasons for considering that a National Standardizing Laboratory for Electrical Instruments had become an absolute necessity, and that the operation of the Acts of Parliament laying down the conditions for the public supply and sale of electrical energy required for their complete working the means of obtaining authoritative expression of the values of the measurable magnitudes there referred to as pertaining to the supply of electricity. And, in short, that as the Legislature had interfered to regulate the conditions under which electric energy should be publicly sold, so it was in consequence necessary that it should provide the means for legally determining the correctness of the instrumental appliances by which it is sold. The suggestion so made commended itself strongly and at once to the Members of the Institution, and a unanimous resolution recommended the appointment of a Committee to examine the means by which some practical form could be given to this idea. We believe that after some tentative schemes had occupied the attention of this Committee of the Institution, it was found that the necessity of developing these desires into fact had forced itself also upon the attention of the Electrical Section of the London Chamber of Commerce; and the final outcome

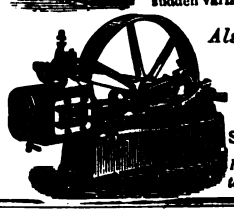
"D&S." PATENT PORCELAIN ELECTRIC LIGHT FITTINGS.
ADOPTED BY THE PRINCIPAL Electric Light CONTRACTORS
SWITCHES, CUT-OUTS, LAMP HOLDERS & OTHER ACCESSORIES.
DORMAN & SMITH. Brazenose St., MANCHESTER.

E. P. & W. BALDWIN,
Works:—WILDEN, near STOURPORT.
MANUFACTURERS OF
PURE CHARCOAL SHEET IRON, SUITABLE FOR ELECTRICAL PURPOSES.
London Agents: BROOKER, DORE & CO., Corbet Court, LONDON, E.C.

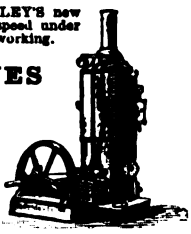
ELECTRIC CRANES,
TRAVELLING, PORTABLE, AND FIXED.
R. BOLTON & CO., Engineers,
110, LEADENHALL STREET, LONDON, E.C.

To Inventors, Patentees, and the Trade.
Mechanical Work of every Description.
PLANING, BORING, TURNING, & SCREW CUTTING.
PRESS TOOLS.
WHEEL CUTTING & RACKS FOR ARC LAMPS.
CARL OPPERMANN, 41, SIGDON ROAD, HACKNEY, N.E.

E. S. HINDLEY,
ENGINEER.
London Show Rooms and Stores— 11, QUEEN VICTORIA ST., E.C.
Works— BOURTON, DORSET.
STEAM ENGINES
HORIZONTAL, VERTICAL, PORTABLE AND FIXED.
SPECIALLY SUITABLE FOR ELECTRIC LIGHTING PURPOSES.
Small Engines for Installations of 6 20 c.p. and upwards.
ECONOMICAL TO USE. MODERATE IN PRICE.

These Engines are controlled by E. S. HINDLEY'S new Governor, which maintains a perfectly uniform speed under sudden variations of work, and is adjustable when working.


Also STEAM ENGINES FOR ALL PURPOSES.
SAW BENCHES,
PUMPS.
SHAFTING, PULLEYS, &c.
Illustrated Catalogues, Photos, and detailed Information free on application.



ADDRESSES.

LAING, WHARTON, & DOWN, 82a, NEW BOND-STREET, LONDON, W., Electric Light Engineers & Contractors. Sole Operators for England of the Thomson-Houston system of Arc Lighting. Special Agents for the Edison-Swan Co.'s Incandescent Lamps and Apparatus. Manufacturers and Suppliers of every requisite for Arc or Incandescent Lighting, Dynamos, Lamps, Switches, Electroliers, Brackets, &c. Specialities in Primary Batteries for Electric Lighting. Venetian Shades and Glass, Carbons, &c. Temporary lighting on any scale at short notice. Estimates free. Telephone No. 3602.

JULIUS SAX, Electrical Engineer and Electric Light CONTRACTOR, RIDGMOUNT STREET, STORE STREET, LONDON, W.C.
Established 1855.
Specialities—Electric Bells, Burglar Alarms, Fire Alarms, Watchmen's Clocks and Fire Indicators combined, Water Gauges, Billiard Markers, Electric Vanes, Lightning Conductors, Speaking Tubes, Gas Lighters, Electrical Testing and Telegraph Instruments, Electrical Torpedo Apparatus.
Automatic Call Bells for Fire Stations, &c., fixed at all Stations under the control of the Metropolitan Board of Works.
Call Calls for Police Stations, Prisons, &c., as devised for and adopted by H.M. Home Office. Contractor to H.M. Post Office and War Office.
Electric Lighting—Domestic and Public. Estimates Free on Application.
Eight Prize Medals awarded.
Telephone No. 3843. Telegraphic Address: "*Sax—London.*"

WALTER T. GLOVER & CO., Electric Wire and Cable Makers, SALFORD, MANCHESTER. Works: Bridgewater-street, Broughton-road, Salford; Salford Electric Wire Works, Salford; Springfield-lane Cable Works, Salford. Established 1868. London Address, 10, Hatton-garden, E.C.; Telegram, "Phonoscope," London; Telephone No. 6691. Manchester—Telegram, "Walter Glover," Salford; Telephone No. 1187.
Specialities—Glover's patent covered Gutta Percha Wire for Leading-in, Tunnel, and Underground Work. Specially covered Iron and Copper Wire for Aerial Lines. Fancy covered single and Double Copper Wire (Paraffined) for Telephonic and Bell purposes. All classes of Silk and Cotton covered Wires for Instruments and Dynamo Machines, Glover's Patent Electric Light Leads and Cables for the various systems.
All descriptions of Covered Wire and Cables for Telegraphic, Telephonic, and Electrical Work, as supplied to the Post Office and the principal Railways. Electric Light, and Telephone Companies.

LAURENCE, PARIS and SCOTT, Limited, Electrical ENGINEERS and CONTRACTORS, GOTHIC WORKS, KING-STREET, NORWICH. Dynamos, Motors, Automatic Cut-Outs, Back Current Cut-Outs, Excess Alarms, Multiple Switches, and Switch Boards. Complete Electric Lighting Plants. Central Station Plants. Estimates on Application.

PHILLIPS BROS., Electrical Wire Manufacturers, The Lea Telegraph Works, HACKNEY WICK, LONDON, E., late of Macintosh-lane, Homerton. Established 1870. Telephone No. 5422.
Specialities—Gutta Percha, India Rubber, Compound, Cotton, Silk, Flexible Cords, Telephone Wire, &c., &c. Multiple and other Wires. Special Wires for Dynamo Machines. Electric Light Leads, &c. Patent Non-Inflammable Insulation for Incandescent and Arc Lighting and Dynamo Machines.

THE LONDON ELECTRIC WIRE COMPANY, ANCHOR WORKS, PLAYHOUSE-YARD, GOLDEN-LANE, LONDON, E.C. (Late of Wenlock-buildings, Ironmonger-row, E.C.)
Specialities—Covered Wires of all descriptions for Electrical Instruments, Dynamo Machines, Bell and House Work, &c. Fancy Paraffined Wires specially prepared for Telephone and other indoor connections.

JOSEPH BOURNE and SON. Works: DENBY POTTERY, nr DERBY. London: NEW ST. PANCRAS STATION.
Manufacturers of the well-known Stoneware Telegraphic Insulators and Battery Jars. Brown Stoneware. White Stoneware. Brown Porcelain. Porous Cells. Economy, strength, durability, and perfect insulation combined. Prize Medal, Paris Electrical Exhibition.
Makers of Mr. Slater Lewis's Patent Self-Binding Insulator.

J. G. STATTER and CO., Limited, Engineers, ALLIANCE ENGINEERING WORKS, WEST DRAYTON. London Offices, Prince's Mansions, 68, Victoria-street, Westminster, S.W. Dynamos and Motors for all Purposes. Perfect Constant-Current System of Arc Lighting. Estimates free. Write for Lists.

PATERSON and COOPER, Electric Light and Power and Telephone Engineers. EUROPEAN WORKS, POWNALL ROAD, DALSTON (Near Haggerston Station). Contractors to H.M. Government, Leeds Corporation, &c.
Specialities—Phœnix Dynamos, Pilsen, Phœnix, and Clark-Bowman and J. F. Arc Lamps, Cardew's Voltmeter, Paterson's Electromagnet Am- and Voltmeter, Ayrton-Perry Am- and Voltmeters, Wallace Diamond Carbons, Switches, Safety Junctions, and Fittings for Arc and Incandescent Lighting. (Removed from 76, Little Britain, since Nov. 16, 1885.)

was a united action on the part of the two bodies to secure a highly influential and representative deputation to the Board of Trade, at which Sir William Thomson, as President of the Institution, Lord Rayleigh, Mr. Crompton and others, laid before the President of the Board of Trade the imperative reasons for taking action in this matter.

It is gratifying, therefore, to all who recognised for the last five years the desirability of this Laboratory to find that Major Cardew is able to speak of this Standardising Laboratory as on the way to become an accomplished fact; and that, to quote his own words, "the Board of Trade have undertaken to provide something in the nature of a testing establishment for instruments intended for the measurement of electrical quantities, and that they have taken powers under the Weights and Measures Act of last Session to undertake such testing and verification and to charge fees for it; so that these verifications, whatever their scientific value, will possess a legal value." It will be seen from this and from the remarks which follow in Major Cardew's Paper that the outlines of the new Laboratory are being drawn in a modest and unpretentious manner; and that the electrical standardising operations are to commence on a scale which, while allowing them opportunity to justify the expectations of their advocates, at least in parts, will deal gently with the feelings of the taxpayer and not give occasion for anxiety to my Lords of the Treasury.

We have no fear, however, that the utility of the Laboratory will not amply justify the establishment of it. Our French and German neighbours have started more ambitious undertakings; and by the side of the Laboratory in the Place St. Charles the scheme outlined to us the other evening has, perhaps, a somewhat one-horse aspect. There are excellent reasons, however, for pitching the note low at the initiation of a scheme such as this; and not the least of these is that it is to such restraint that we are indebted chiefly for the fact that it is realised at all. As the Laboratory proves itself able to meet a definite want, it will certainly be extended. There are two or three conditions, however, which will determine that rate of growth. It is essential, in the first place, that it should be adequately provided with instrumental appliances for doing with the highest degree of perfection that which it undertakes to do. There ought to be no cheeseparing policy in the first outlay for the outfit of the Laboratory. Major Cardew tells us that the first operations will be a series of redeterminations of the practical units. He does not say whether these redeterminations will be made at the Standardising Laboratory itself, or whether the resources of other institutions will be laid under contribution. Considering the experimental difficulties, and the vast labour attending such redetermination, we can hardly suppose that he contemplates a redetermination *ab initio* of the ohm, the electro-chemical equivalent of silver and the specific resistance of mercury. He tells us that the Board of Trade are not bound to the so-called legal ohm. If, however, there is to be another change, it is devoutly to be hoped that it will be a final one, and that it will be taken with sufficient consensus of opinion to make it so. We are now in possession of a British Association ohm and a Paris Congress ohm; if we add to this a Board of Trade ohm, let us at least hope that this last will be a sufficiently approximate realization in the flesh of the ideal 10^9 centimetres per second, not to require touching up again at least during this century. For practical people the question that overshadows all others is the permanence of the standards. Whatever is selected must be adhered to, otherwise cargoes of instruments will continually be relegated to that category in which they are spoken of slightingly as "our old pattern." Another matter of supreme importance will be the selection of observers of trained accuracy, who will be the actual persons engaged in making the comparisons. We feel sure that with Major Cardew's scientific and practical training, aided, if need be, by consultation with others, the methods finally adopted will be the best, and the standards of comparison be prepared and maintained with the greatest care. When all this is said and done, there still remains the actual comparison of the submitted instrument to be made with the authoritative standard; and the value of the certificate will entirely depend on the care with which this is done. We hope that neither in men nor in materials will the new Laboratory start insufficiently equipped, and that entire confidence will be widely diffused in its accuracy from the very first.

The remarks which Major Cardew makes as to the limits of the accuracy aimed at are dictated by sound common sense. It is much easier to talk about one-tenth per cent. error in an electrical instrument than to detect it, far less to remain within that limit. An accuracy of a quarter per cent. will be quite sufficient for practical purposes if that range of comparison is maintained. A great part of the work of that Laboratory will probably be in checking and certifying the sub-standards to be employed by the "electrical inspector" of the future. As Major Cardew says, the appearance of this new functionary will be like the dawn of a fresh species; and it is to be hoped that no pains will be spared in providing him with his weapons of offence and defence. In some far distant time the fossil remains of an electrical inspector will no doubt be exhumed by future archæologists, accompanied by the fragments of something which experts of the twenty-first century will oracularly pronounce to have been one of those rudimentary forms of voltmeter employed towards the end of the nineteenth. An electrical Owen of future days will "restore" the outlines of this instrument from some element, perhaps still retaining a trace of the Board of Trade stamp. To maintain a practical uniformity amongst these instruments of inspection, and to check such sub-standards as are sent in by makers, as well as the electric supply meters which may be required as standards, will keep the new Laboratory busy for some time to come. We venture to prophesy for it a career of great usefulness; and in another five years we may, perhaps, look for a Paper from Major Cardew, to be read before the Institution, describing its operations when in full swing, thus completing a trio in which its inception, its inauguration, and its completion are described.

ELECTRIC RAILWAY POWER TESTS.*

BY IRVING HALE.

The following tests were made last February on the South Broadway Electric Road (Sprague system), Denver, Colo., with a view to determining the amount of power required at various speeds and under various conditions, the various causes of waste of power, and the remedies for these losses. More particularly it was desired to establish the correctness or incorrectness of two theories that seemed justified by abstract considerations:—First: That it is economical to run at as high speeds as practicable. Second: That power will be saved by using one motor instead of two whenever conditions allow.

The tests in Denver were made as follows:—The power plant consists of a 60 horse-power Armington and Sims engine, running a 40,000 watts Edison dynamo.

The car tests were made at night, when no cars except those experimented on were running. In each test the car was run in both directions over one-tenth mile of almost level track, and a mean of the two results taken. On the car the time was taken; at the stations the ammeter was read, the potential being accurately maintained at 500 volts. The total resistance of the circuit was mea-

* From the *Electrical World*.

Digitized by Google

sured with car at middle of the one-tenth mile, the wire from trolley being connected to ground wire in car, thus including all resistances that might exist in the trolley, track-frame and wheel contact with rails. From this resistance and the current readings the loss in line was computed, and was deducted from power at station to give power at car. The car was first run over the course both ways with the controlling switch successively in each of the different positions, both motors being in use. The same runs were then made with one motor cut out but turning, the raw-hide pinion being left on. The pinion was then removed and the same tests repeated. On another occasion runs were made first with one motor cut out, but with its brushes in, and then with the brushes removed, the idea being to detect any possible loss in the way of local current, friction, &c., due to pressure of brushes. There was no appreciable difference above what might be due to errors in observation.

The power actually required to run the car at various speeds was approximately determined by two methods, as follows: Another car was run over the course in both directions at different speeds and readings taken. This car then hauled, at about the same speeds, the car on which tests were to be made. The two power curves being plotted, the difference in their ordinates at various abscissæ (representing speeds) should give approximately the power required to haul the towed car at these speeds. By the other method, the car to be experimented upon was run at various speeds and timed over a measured course just before reaching the $\frac{1}{10}$ mile course, when the current was thrown off and the car allowed to run until brought to rest by the resistance. The experiment was then repeated in the opposite direction. The energy of the car at the computed velocity being overcome in a measured distance by the car resistance plus the grade resistance when going up, and by the car resistance minus the grade resistance when going down, the coefficient of friction or resistance and the inclination of the grade could be computed without knowing the weight of the car, which appears as a factor in both members of the equations. This gives the average resistance of the car while slowing down, or approximately the resistance at one-half the maximum speed. The highest speed observed was 14·7 miles per hour, so the coefficient determined applies to speeds of 7·4 miles and under. The results of different observations by this method agree quite closely with each other, as do also the computed values of the grade. The weight of the car was not accurately known, but computing from known weight of motors and truck, and assumed weight of car body, the total weight with the occupants was about five tons. Curve A (Fig. 2) represents the power, computed on this basis, required at speeds below 7·4 miles an hour, while curve A′ shows power required at speeds between 10 and 13 miles per hour computed by the first method. These two curves, although not covering the same speeds, appear to agree quite well, and by joining them by the supposititious dotted line, a curve is obtained that corresponds quite well with the form that would be expected.

These tests for resistance, made on the same night as the speed and power tests, were not satisfactory, and another set was therefore taken on another night. To detect and allow for any difference in resistance on the two nights, due to different condition of bearings, track, &c., a set of speed and power tests was also made on the second night, and their curve plotted alongside the first night's curve. It was nearly parallel to the latter, and from ·3 to ·7 horse-power above it, the difference increasing with the speed. These corrections, subtracted from the resistances on the second night, give what would have been the resistances on the first night, and it was from the corrected values thus obtained that the curves A and A′ were plotted. If the motors and gearing were removed from the car, this curve would be considerably lower. It could approximately be determined by making the hauling test with both main gears removed, and then allowing a proper correction for weight of motors. Time did not permit this test to be made.

With the foregoing statement of methods employed, the tables and curves require little further explanation.

Station Tests.

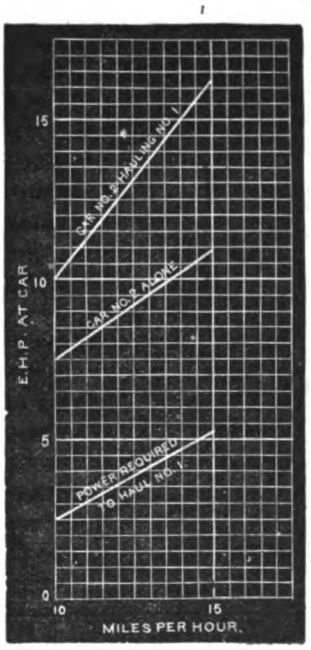

FIG. 1.—Power required by cars.

Figs. 2 and 3 are plotted from Table III. The curve A A′ is obtained as explained above, and is to be considered in connection with curve D. The actual power required to haul car with one motor ungeared should have been obtained in the same manner; but as this was not done, the hypothetical curve *a′* was constructed by subtracting from the ordinates of A′ the corresponding difference between ordinates of B and C, which ought to represent power saved by ungearing one motor. Fig. 3, plotted from Column 5 of Table III., requires no explanation.

Figs. 4 and 5 result from a combination of the preceding figures. Fig. 4 represents a supposititious case of road equipped, like this road, with a 60 horse-power engine and a 53 horse-power dynamo, operating four cars with two motors each, and shows the conditions at different speeds, all four cars running at same speed. Fig. 5

Digitized by Google

shows the same plant operating eight cars with one motor each, which will require about the same maximum power.

Discussion of Curves and Tables.

Figs. 2 and 3 show the decided saving in power effected by cutting out one motor, especially if its pinion be removed. Fig. 3 shows that the horse-power hours or power consumed per mile run varies but little with the speed. Consequently, by running at high speeds, a given number of miles will be covered in a day with about the same expenditure of coal, and with fewer cars, drivers and conductors, thus reducing cost of equipment, interest on investment, and wages of attendants, while the public will get faster transit.

Fig. 2.—Relation between power and speed.

General conclusions can best be drawn from Figs. 4 and 5, which show graphically the causes and amounts of the various losses. In the first place it should be borne in mind that these curves, representing as they do a supposititious case, where all the cars are running at uniform speed, do not by any means tell the whole story. It is only necessary to stand in the station and watch the sudden variations of the ammeter and the efforts of the engine to keep a steady gait when several cars start at once, to be convinced that there should be a good margin of power allowed in the station equipment, and especially that the engine should be strongly built, heavy, and have a much larger fly-wheel than is usually provided to aid in carrying it smoothly over the rough places.

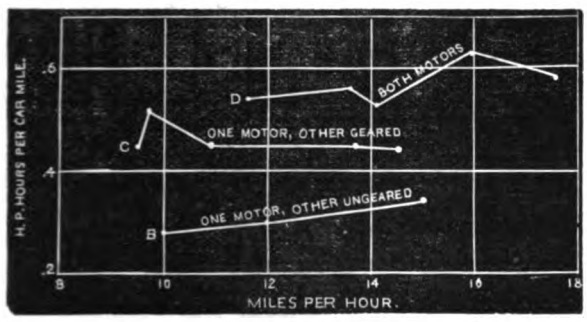

Fig. 3.—Relation of h.p. hours to speed.

In Figs. 4 and 5 the difference between curves G and E represents loss in engine and dynamo friction, which is assumed to be constant, and is about 15 per cent. of the normal power of the engine. Engine and dynamo friction were not separated in test, and curve F is constructed on the supposition that two-thirds of friction is due to engine and one-third to dynamo. The space between E and D shows electrical loss in dynamo about 9 per cent. of load. The difference between D and C represents loss in line, which in this case is very small, and in a properly designed line should not as a rule exceed 10 per cent. The difference between C and B shows electrical loss in motors. The space between B and A shows loss chargeable to friction of motor and gearing.

Remedies.—The friction of engine cannot probably be decreased very much, but as it is of much greater importance at low load than at full load, it is evidently desirable always to run as near full load as possible, consistent with a safe margin for sudden strains. On a road with varying traffic this can be accomplished only by having several dynamos and engines, running at any time only as many as are necessary to give the required power and margin. This is an argument in favour of using a number of high-speed engines coupled direct to dynamos, instead of one or two large low-speed engines with counter-shafting. The same remarks apply to loss in dynamo friction.

FIGS 4 & 5

Fig. 4.—Diagram of Losses. Double motors. Four cars, two motors each.

The present dynamo is a very efficient machine, and no very great improvement can be looked for. The loss in line is simply a question of copper, and must be decided on the basis of waste of

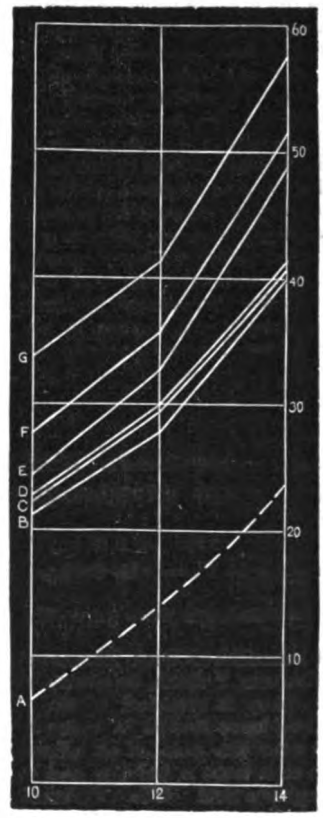

Fig. 5.—Diagram of Losses. Single motors. Eight cars, one motor each, other ungeared.

power versus interest on first cost, care being taken not to allow such a percentage of loss, even if dictated by theoretic economy, as to give unsatisfactory service at most distant parts of line. The electrical loss in motors is as small as can reasonably be expected.

Digitized by Google

The greatest loss of all appears to be in the mechanical means employed to transmit the real power exerted by the motor to the wheel. The obvious remedy is to reduce the gearing to a minimum, and the first step is to concentrate the working force in one motor. The great saving effected by this is plainly illustrated in Figs. 2, 4, and 5, which show that cutting out one motor and removing its pinion reduces the power required nearly one-half, and that eight cars thus treated can be run at a given speed on the same indicated horse-power as four cars with both motors running.

There are, however, some arguments in favour of two motors that must not be overlooked. First—They guard against accidents. But in the present state of development of the street car motor it is believed that such accidents are not sufficiently frequent to make the game worth the candle. Second—On many roads one motor is insufficient to do the work occasionally or frequently imposed. The remedy for this is to make the motor larger. The contracted space under the car places a limit on increase in size; but considerable increase can be made, and it must be remembered that owing to the smaller *waste* of power in the single motor, it need not have as much nominal power as the two motors, in order to do the same work. If it is found impracticable to make a single motor large enough to do the work on some roads, then, in those situations, two must be used, but in many places one would suffice. Third—On very steep grades it is advantageous to have a motor on each axle, as the adhesion of all four wheels is thus utilised for traction. But there are many roads where this is unnecessary. Most roads with heavy grades requiring two motors would require only one over the greater portion of their length. This suggests the desirability of being able mechanically to throw in one or both motors at will, the idle motor being ungeared.

The conclusions suggested by the preceding tests would seem to be these:—Use high-speed engines having extra strength and weight and heavy fly wheels. Design power station so that under all conditions it may be possible to have just enough engines and dynamos running to give the required power with a safe margin. Put up a liberal system of line feeders, and be sure that in adding cars to the equipment the line loss does not become objectionably great. Run at as high speed as the law allows. If cars are equipped with two motors, run with one of them cut out and its pinion removed, provided the maximum work is within the capacity of one motor. On roads with light grades and moderate speeds and loads, equip cars with one motor, making it larger than 15 horse-power if necessary. Avoid, however, being led by these theoretical considerations into the error of providing insufficient power to meet the greatest demands that will be made upon the motors.

As to possible future developments, these observations point to the concentration of power into a single motor and set of gearing on which shall be spared neither careful workmanship, expense, nor weight necessary to make it thoroughly substantial and trustworthy; to the desirability of a simple and efficient mechanical contrivance, by which either or both of two motors (when two motors are necessary, either to give required power or utilise the adhesion of all four wheels) may be thrown in or out of gear, and lastly to the possible desirability of a motor without gearing, with armature attached direct to axle. For street-car speeds it is probable that the electric difficulties, increased size and weight of such a motor may always outweigh the gain secured by abolition of gearing; but when high speed railway trains are run by electricity, as they certainly will be before long, it is not unlikely that the advantage will be reversed.

ON PROF. ELIHU THOMSON'S ELECTRO-MAGNETIC INDUCTION EXPERIMENTS.*

By J. A. Fleming, M.A., D.Sc., M.I.E.E., Professor of Electrical Engineering in University College, London.

(Continued from page 61.)

One of the most beautiful of Prof. Thomson's experiments illustrating this repulsion can, I think, be shown to you now.

An incandescent lamp is attached to the terminals of a coil of wire, and the coil and lamp floated in water or hung from a scale beam (*see* Fig. 24) over the pole of an alternating magnet. The coil and lamp form as it were a balloon and car floating in space, and placed in a magnetic field. When that magnetic field is rapidly alternated by exciting the magnet, the induced currents created in the coil make themselves evident by illuminating the lamp, and the repulsive electro-dynamic action shows itself by lifting the lamp and coil upwards through the water or the air.

The same experiment renders it possible to show the effect of magnetic screening very prettily. If I introduce a plate of copper between the magnet pole and the induction coil attached to the lamp, the copper "screens" the coil from the inductive action of the pole, and the light of the lamp disappears. I must next direct your attention to some curious effects which are found to exist when two conducting circuits are exposed to the magnetic flux from an alternating magnetic pole, and which depend upon the interaction of the currents induced in each respectively. Prof. Thomson embodies these facts now to be considered in four laws, which may be briefly stated as follows:—

1. If two or more closed circuits are similarly affected inductively by an alternating magnetic field they will attract one another, and tend to move into parallelism.

2. Iron or steel masses placed in an alternating field give rise to shifting magnetism or lines of force moving laterally; and may, therefore, act to move closed circuits in the path of such shifting lines.

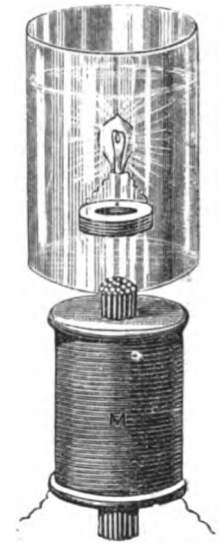

Fig. 24.

3. Closed circuits in alternating magnetic fields or fields of varying intensity give rise to shifting magnetism, or lines of force moving laterally to their own direction; and may, therefore, act to move other closed circuits in the path of such lines.

4. Iron or steel masses may, when placed in an alternating magnetic field, interact with other such masses, or with closed electric circuits, so as to produce movement of such masses or circuits relatively, or give rise to tendencies to so move, the effects depending on continual adaptations of shifting magnetism and retained magnetism relatively.

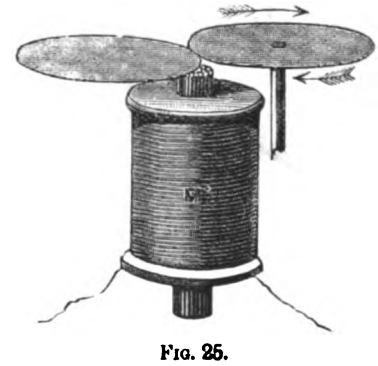

Fig. 25.

It is a simple matter to illustrate these principles; and the experiments which are designed so to do bring before us some striking peculiarities of the action of magnetic force upon closed circuits and upon masses of conducting and magnetisable matter.

Returning, first, to the simple experiment of a copper ring repelled by an alternating pole, we find that if we add a second ring under the first they both attract one another, and the two rings are supported and repelled as if they were one ring. It is obvious that at any instant the induced currents in both rings are in the same direction, and hence they attract one another.

Such an attractive action can be made to produce continuous rotation. We have only to place a copper ring or plate over the alternating-current coil or pole, and then bring a copper disc, free to revolve on pivots, into proper position relatively thereto. This can best be done by placing the ring or plate so as to be somewhat to

* A Paper read before the Society of Arts, May 14, 1890.

Digitized by Google

one side of the pole, so as to "shade" part of it, as it were, while a part of the pivoted disc is placed under or over it, in front of the alternating pole. The disc then begins to revolve rapidly on its pivot (*see* Fig. 25). A little consideration shows that in this case the fixed copper plate shields a portion of the pivoted plate. The currents induced in the fixed plate attract the non-symmetrically placed induced currents in the other disc and set up a tangential action or couple upon it, tending to pull it round. The continual repetition of this action as each portion of the plate becomes in turn the seat of maximum inductive action, results in a continual revolution of the plate. Two pivoted discs may be used instead of one, and it will be found that they may each "shade" a portion of the pole, and, if made to overlap, they will pull each other round and revolve in opposite directions when the alternating pole acts upon them.

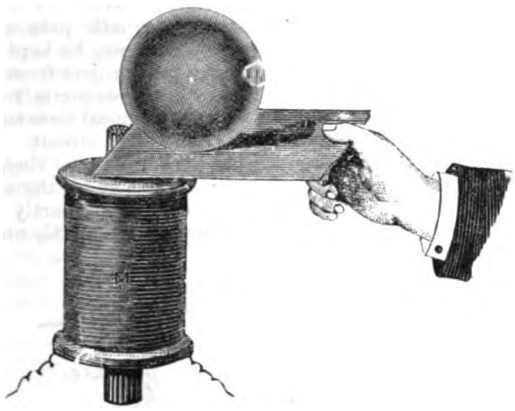

FIG. 26.

This principle of "shading" a portion of the magnetic pole, and hence causing an unsymmetrical distribution of induced currents in a conducting body capable of revolution on a pivot, has been developed by Prof. Thomson in many extraordinary ways.

Floating, for instance, a hollow sphere of copper on the surface of water in a glass vessel, he places this over an alternating magnetic pole. If the pole is placed directly under the sphere, the electro-magnetic action would, as before explained, result in a repulsive force acting upon the disc. If, however, a sheet of copper is placed half over the pole so as to "shade" a portion of the copper sphere, the currents induced in it are unsymmetrically situated with respect to its centre, and react upon the current induced in the plate. Hence, the electro-magnetic action resolves itself into

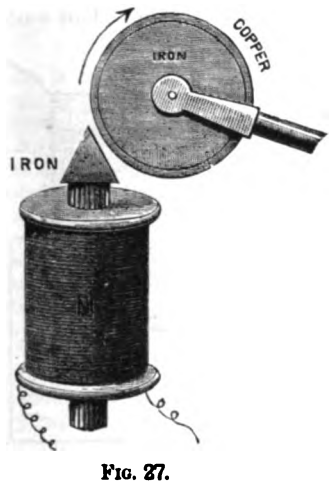

FIG. 27.

a torque or couple, causing the ball to spin rapidly upon its centre, and take up a rapid rotation. So considerable is the rotational force brought to bear that the ball will rotate when merely laid on a sheet of copper, even overcoming the friction of such rotation on its equatorial line, provided that the ball and supporting plate are so held over an alternating pole that the plate shields a portion of the sphere (*see* Fig. 26). Given this principle that by properly "shading" a pole from a portion of a solid body capable of revolution round a line or axis, it is easy to see that countless forms of electromotor can be designed.

A sort of anemometer with copper discs for cups resembling the cross of a Crookes' radiometer can be set in rapid rotation by an alternating pole, if a copper screen be placed so as to shade one side of it.

This unsymmetrical development of the induced currents can be produced by a suitable disposition of the magnetic pole alone. Thus we may place a cone or wedge of iron on the alternating pole, and hold near it a copper ring mounted so as to be able to revolve (*see* Fig. 27). The copper cylinder or wheel revolves rapidly under the action of the periodic field, and its direction of motion is such that it seems to be blown around by a blast from the end of the magnetic cone. Prof. Thomson has constructed a curious electrical gyroscope as follows: a vertical pivot projects from the centre of an alternating pole (*see* Fig. 28), upon which is pivoted a horizontal rod bearing a counterpoise, and a copper wheel preferably with an iron core attached to it, gyroscope fashion, by means of a copper frame. The copper frame is placed in an inclined position with respect to the horizontal. Under these circumstances a vigorous rotation is

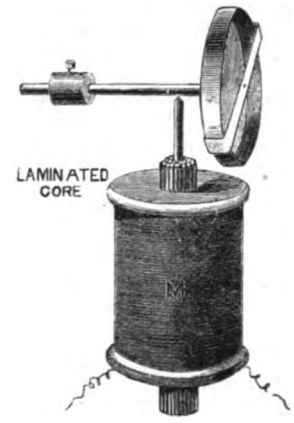

FIG. 28.

communicated to the gyroscope wheel when the alternating field acts upon it. The copper frame shields one side of the wheel more than the other, and as a result the induced currents in the copper wheel are unsymmetrically placed with respect to its axes of rotation, and it experiences a violent torque.

These experiments can, by a little ingenuity, be endlessly multiplied when once the fundamental principle is grasped. Bodies can be made to rotate and move, taking their movements from the magnetised space in which they are placed, and without being supplied with current from an external source.

Prof. Thomson has, however, studied some curious cases of magnetic motion in which rotations are obtained when iron or copper pivoted discs are placed near to iron or steel bars in which the propagation of magnetism is throttled by closed circuits. If a longitudinally laminated iron bar has a closed copper band or coil placed round it at one point, and if such a bar is made magnetic by a periodic current traversing a magnetising coil embracing another part, this structure becomes capable of rotating iron or copper discs held near it. The explanation of this effect is probably to be found in the fact that the closed embracing coil tends to throw off the magnetic lines of force laterally at that point. Consider a bar (Fig. 29) A B, in which lines of magnetic force are being established in the direction from A to B. That is to say, let magnetic induction be increasing in the bar in a direction from A to B, at C let there be a closed

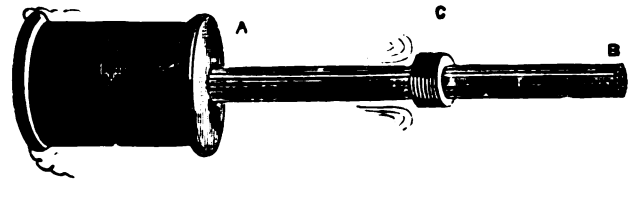

FIG. 29.

coil embracing the bar, the magnetic induction during its period of increase is setting up in this circuit an electromotive force which establishes in the circuit a current whose lines of force are opposed to the primary induction inside the coil, and therefore in the iron included in the coil, but in the same direction outside the coil, and therefore outside the iron. The result is as if the lines of primary magnetic induction in the iron were shed off laterally and escaped round the coil. When the magnetic induction in the iron, due to the magnetising coil, is made periodic, this action will create a kind of lateral pulsation of the magnetic lines of force in the neighbourhood of the closed coil. If, then, a moveable conductor is held near such a magnetically throttled bar, it will be subjected to a displacement of lines of magnetic force through it laterally, and will hence have eddy electric currents generated up

Digitized by Google

in it. These currents, persisting into the period of reversal of the field in virtue of self-induction in the conductor, will cause the portion of the conductor in which they are set up to be continuously repelled, and hence to take up a motion of rotation. A ring of cast-iron having a closed coil wound on it at one point, is held so that another point on its circumference 90deg. removed from the closed coil, is on the pole of an alternating magnet. An iron disc centrally pivoted and held concentric with the ring, is rotated when the magnet is energised by an alternating current. It is not even necessary to have a closed coil on one part of the active magnetic bar, provided that this bar is not laminated, or, better still, is made of hard steel. In these cases there is a lag in magnetisation due to either eddy currents set up in the bar or to hysteresis, and the result is a lateral escape of lines of force out of the bar when it is held with one extremity on an alternating magnetic pole. Then there is in these cases an action which is a true "magnetic self-induction." In the case of electric circuits, if we join in parallel two circuits, one having very small ohmic resistance and very high self-induction, and the other very large ohmic resistance and small self-induction, a sudden flow of current chiefly selects the path of least self-induction for its flow during the variable period, although

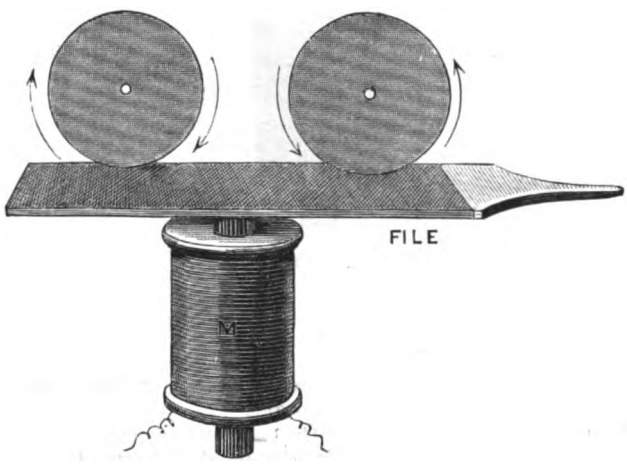

Fig. 30.

during its steady period it will chiefly flow by the path of smallest ohmic resistance; so in the case of a magnetic and conductive circuit of low magnetic and electric resistance (iron), shunted by a path of high magnetic and electric resistance (air), rapid variations of magnetic induction bring about a state of things in which the magnetic induction seems to chiefly select the

Fig. 31.

path not of least but of greatest magnetic resistance during the variable period. Time will not permit me to develope at greater length the analogies of the magnetic and electric circuits under the conditions of rapidly periodic magnetic induction and electric current; but there are many suggestive ideas which arise when we place before our minds the notion of a magnetic self-induction which is the consequence of a time-element coming into action in the setting-up of induction in a magnetic and conductive circuit, and due to the production of electric eddy currents, just as the electro-magnetic or ordinary self-induction is the consequence of the time element coming into action in the setting up of an electric current, and due to the production of a surrounding magnetic field. Just as the rise of current strength under an impressed electromotive force acting in a conducting circuit is retarded by linking that conductive circuit with a magnetic circuit, so the rise of magnetic induction under an impressed magnetising force, acting on a magnetic circuit, is retarded by linking that magnetic circuit with an electric conducting circuit. I am under the impression that Mr. Oliver Heaviside has developed these notions in a mathematical form, but am unable at the moment to place my hands on the results. The effect, however, of a bar of unlaminated iron when surrounded by a magnetising coil at one end and traversed by a periodic current is to cause rotation in copper or iron pivoted discs held near it, or when such a bar of non-laminated iron is abutted on the pole of an alternating magnet. A bar of steel, even if not laminated, is able to cause brisk rotations in copper or iron discs under the same circumstances. With hardened steel the action is more marked. Here the hysteresis retards the propagation of the magnetic wave. By laying a large file flatwise against the alternating magnetic pole at about the middle of the file, discs of copper or iron may be kept revolving if held over those portions of the file which project from the pole of the magnet (*see* Fig. 30). In this case the magnetic retardation in the bar is brought about by its own chemical structure, and not by embracing it with a closed conducting circuit. The result is, however, the same in kind; there is a sluggishness in the establishment of the magnetic induction on the steel or iron under the action of magnetising force which partly depends on eddy currents in the mass of the metal and partly on hysteresis.

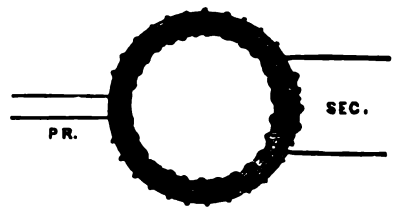

Fig. 32.

As a consequence we have a periodic lateral displacement of the field. This question of a magnetic leakage dependent on a retardation of induction deserves special attention in the case of commercial alternate-current transformers. Time will not permit me to enlarge on it here to any great extent; but I may observe that in the design of closed-iron circuit transformers this magnetic leakage should not be neglected.

In a closed iron circuit embraced at one part by a magnetising coil and subjected to rapidly reversed magnetic force, the magnetic induction does not confine itself wholly to the path of least magnetic resistance, viz., the iron path, but takes a short circuit in part across the interior air space. This waste field may in badly

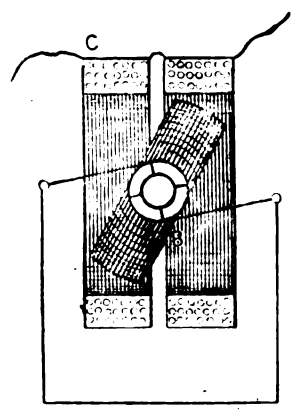

Fig. 33.

designed transformers be something considerable. I believe that an important point to hold in view in transformer construction is to subject the iron circuit uniformly to the magnetising force, by embracing all portions of the iron circuit with primary windings, and not locating the windings simply at one part. There is then a tendency to check the production of waste field by the lateral budging-out of the magnetic lines of force from the iron. In Fig. 31 is a diagram illustrating the arrangement primary and secondary coils most favourable for the production of waste field, and in Fig. 32 the arrangement least favourable for the same.

The foregoing experiments are of such a nature as obviously to force on us the thought that useful and perhaps important applications can be made in electro-magnetic machinery. Professor Elihu Thomson has, as you can imagine, not been slow to do this; for in

Digitized by Google

him is united both a keen scientific sagacity and that clear mental vision which enables him to pursue to its logical issue in practice the consequences of scientific discovery. He has already applied these principles to the construction of alternating-current indicators, alternating-current arc lamps, regulating devices for alternating currents, and to rotary motors for such currents. For current indicators, a pivoted or suspended copper band or ring composed of thin washers piled together and insulated from one another and made to carry a pointer or index, has been placed in the axis of a coil conveying alternating currents whose amount or potential is to be indicated. Gravity or a spring is used to bring the index to the zero of a divided scale, at which time the plane of the copper ring or band makes an angle of, say, 15 to 20 degrees with the plane of the coil. This angle is increased by deflection more or less great, according to the current traversing the coil. The instrument can be calibrated for set conditions of use. Time would not permit of a full description of these arrangements as made up to the present.

In arc lamps the magnet for forming the arc can be composed of a closed conductor, a coil for the passage of current, and an iron wire core. The repulsive action upon the closed conductor lifts and regulates the carbons in much the same manner that electro-magnets do when continuous currents are used. The electro-inductive repulsive action has also been applied to regulating devices for alternating currents, with the details of which I cannot now deal.

For the construction of an alternating-current motor which can be started from a state of rest the principle has also been applied, and it may here be remarked that a number of designs of such motors is practicable.

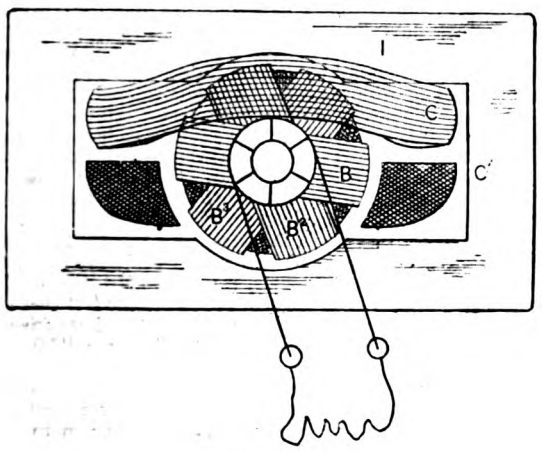

FIG. 34.

One of the simplest is as follows: The coils C, Fig. 33, are traversed by an alternating current and are placed over a coil B, mounted upon a horizontal axis, transverse to the axis of the coil C. The terminals of the coil B, which is wound with insulated wire, are carried to a commutator, the brushes being connected by a wire, as indicated. The commutator is so constructed as to keep the coil B on short circuit from the position of coincidence with the plane of C, to the position where the plane of B is at right angles to that of C; and to keep the coil B open-circuited from the right-angled position or thereabouts to the position of parallel or coincident planes. The deflective repulsion exhibited by B will, when its circuit is completed by the commutator and brushes, as described, act to place its plane at right angles to that of C, but being then open-circuited its momentum carries it to the position just past parallelism, at which moment it is again short-circuited, and so on. It is capable of very rapid rotation, but its energy is small. He has extended the principle to the construction of more complete apparatus. One form has its revolving portion or armature composed of a number of sheet-iron discs wound as usual with three coils crossing near the shaft. The commutator is arranged to short-circuit each of these coils in succession, and twice in a revolution, and for a period of 90 degrees of rotation each. The field coils surround the armature, and there is a laminated iron field structure completing the magnetic circuit.

In Figs. 34 and 35, we have diagrams which will give an idea of the construction of the motor referred to. C C′ are the field coils or inducing coils, which alone are put into the actuating alternating circuit. I I is a mass of laminated iron, in the interior of which the armature revolves with its three coils, B, B^2, B^3, wound on a core of sheet-iron discs. The commutator short-circuits the armature coils in succession in the proper positions to utilise the repulsive effect set up by the currents which are induced in them by the alternations in the field coils. The motor has no dead point, and will start from a state of rest and give out considerable power, but with what efficiency is not yet known. A curious property of the machine is that at a certain speed, depending on the rapidity of the alternations in the coil C, a continuous current passes from one commutator brush to the other, and it thus performs the function of converting some electric energy from an alternating to a continuous form.

A small motor of a curious type has been made, utilising the principle of "shading" the pole by closed circuits. A laminated ring (Fig. 36) is wound over with wire, but has a slot cut through

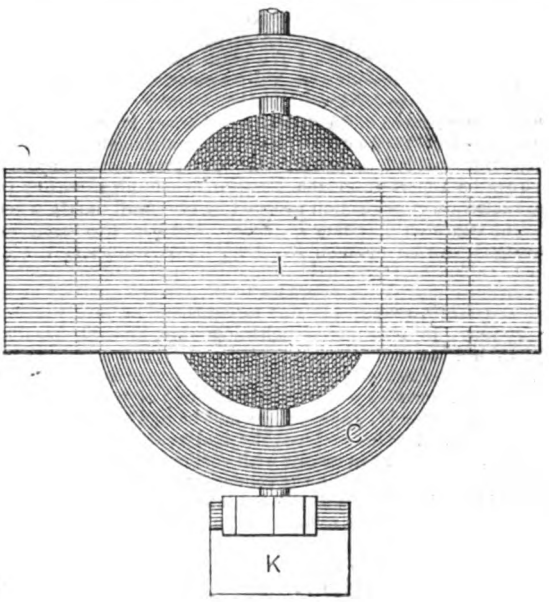

FIG. 35.

it, dividing the ring and causing it to present two pole faces opposite to each other at the cut part. Each pole is arranged by a set of closed copper bands to be "shaded." A copper disc, free to turn on a shaft, is introduced by one edge into the air-gap in the magnet, and turns rapidly when the magnet is excited. A silver coin held just at the edge of the air-gap in such an alternating magnet with shaded poles, is drawn into the interpolar space and propelled with some force through the same; but a lead disc or coin of base metal is not acted upon nearly by the same force, owing to its inferior conductivity. I have left myself but little time to speak of numerous applications of these principles in alternating-current meters. The well-known meter of Mr. Schallenberger was described to you here quite recently by Professor Forbes. There is, however, a new form of meter, designed by Messrs. Wright and Ferranti, which exhibits in a most beautiful manner a practical application of some of those principles which have briefly occupied our attention (*The Electrician*, May 16th, 1890, p. 32.)

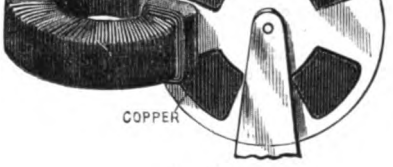

FIG. 36.

It would take me beyond the limits of the time during which I am permitted to trespass upon your attention if I were to attempt to exhaust the list of electro-motor applications that have been made of these electro-magnetic repulsions. That is a subject important enough to deserve a separate treatment. In Berlin, not long ago, I saw a most ingenious form of self-starting alternating-current motor, the invention of Herr von Dolivo Dobrowolsky, in which the rotating portion was merely a solid iron cylinder constituting a commutatorless armature, revolving in an alternating field, and which acted in a perfectly marvellous manner. The region of practical invention here opened is a very wide one: and I have, therefore, ventured to direct your thoughts to it to-night, confident that its character in this respect deserves all the attention it can obtain, and that a firm foundation for it is laid in these interesting researches of Prof. Elihu Thomson.

ON LIGHTNING-GUARDS FOR TELEGRAPHIC PURPOSES, AND ON THE PROTECTION OF CABLES FROM LIGHTNING.

The following is an abstract report of the discussion on the Paper read by Dr. OLIVER LODGE before the Institution of Electrical Engineers, on April 24th :—

Mr. SAUNDERS said he got the idea of his lightning guard in 1864, from noticing that a cable was connected to a land line through a fine wire enclosed in a glass tube. These wires were frequently fused, and the tubes broken, so he replaced the glass tube by a brass one connected to earth. After this fusions were less frequent. Sir W. Thomson brought out a similar device in 1872, quite independently. From the fact that in his practical experience of 25 years he had never known a cable or instrument protected by his guard to be damaged, although the wires had been often fused, he was led to believe that the arrangement was a good one. He then read a report from the Eastern Telegraph Company relating to a remarkable case of protection afforded by his guard during a very sudden and violent storm on February 14, 1888. The wire was fused, but nothing else damaged. In his opinion, Dr. Lodge over-estimates the chances of damage to cables, for instruments and other apparatus are more frequently injured than cables. With reference to Dr. Lodge's question as to whether unexplained faults may not be due to lightning, he said that such faults were very few. Injuries due to lightning were, he said, usually near the ends of cables, but even these were of rare occurrence. As regards Dr. Lodge's guard, Mr. Saunders thought it very ingenious, but before it could be pronounced successful it must stand the test of practical use. In reply to questions from Sir W. Thomson, he said he had never known condensers to be damaged. In the accident he had referred to he could not say whether the cables were in circuit with condensers or not.

Sir W. THOMSON thought the condenser ordinarily used for signalling would be, in conjunction with the Saunders's fuse wire, an efficient protection for cables, for the quantity of electricity required to make the difference of potentials between the plates considerable would probably be more than sufficient to fuse the wire ; hence the cable could never be raised to a dangerously high potential. He asked Mr. Saunders for the particulars of the wires generally used, and was informed that their length was 15 inches, diameter ·0027 inch, and resistance 45 ohms. These, Mr. Saunders said, were frequently fused. Sir W. Thomson (continuing) said that in a lightning discharge it was probable that any free passage to earth would be taken advantage of ; it was, therefore, important to put the fine wire beyond the spark-cap protector. He considered that the new principle introduced in Dr. Lodge's self-inductive conductor, with graded spark-gap, might give valuable security when no condenser is used, and enhanced security even when there is a condenser.

Mr. PREECE said he wished to treat the question from a practical standpoint, but he was willing to admit that some attention must be paid to theory. In his opinion it was quite unnecessary to assume that lightning flashes were oscillatory in order to understand that self-induction may be beneficial in causing a discharge to jump over the spark gap, for all admit the sudden and rapid rise of the flashes ; and this was the only essential point. In considering the question as to whether a necessity exists for a novel lightning protector, he pointed out that such an apparatus should either fill a want, give greater efficiency, or be more economical than the ordinary protectors. With respect to the first condition he maintained that no want exists, for the common protectors answer all requirements. In support of this he quoted the Post Office returns for 1889, from which it appears that out of 600 valuable instruments, such as quadruplex, multiplex, Wheatstone automatics and repeaters, not a single one had suffered damage from lightning. This, he considered, was a strong proof of the efficiency of the methods of protection adopted. The protector consists of two circular plates separated by thin mica, or by a layer of air about $\frac{1}{100}$th of an inch thick ; the self-induction of the working instruments was sufficient to cause the spark to lead across the space. As to cables, he said that all the 117 under his charge were protected by the plate guards above described ; but, in addition, a coil and fuse wire were inserted between the plates and the cable. This method had been in use since 1879, with perfect success. During the interval only one case of damage had occurred, and in this considerable doubt existed as to whether the injury was caused by lightning or not. From these facts he concluded that no want for a new protector exists, and that none can give greater efficiency. As regards economy he said the ordinary protectors cost from 2s. 9d. to 3s. 6d., whilst those for cables were about £1. If anything could be gained by the use of Dr. Lodge's apparatus he (Mr. Preece) would be glad to try it ; but he would also use in addition one of the ordinary protectors which practical experience had shown to be successful.

Mr. CHARLES BRIGHT commented on the remarkable similarity in lightning guards, and said their pedigrees were very interesting. The devices of the earlier workers in the field, Steinheil, Breguet, Faraday and Walker, had been considerably improved by Varley, Siemens, Saunders and Jamieson. Steinheil, he thought, was the first to recognise the fact that the law of divided circuits was not true for rapid discharges. In Dr. Lodge's guard several new principles were involved, the chief of which seemed to be the introduction of self-induction by means of coils ; the protection from damage due to electricity surging up from the earth seemed to him an important feature, in which Dr. Lodge's apparatus differed from that of Mr. Saunders and others. Mr. Bright then directed attention to Sir Charles Bright's guard, and said that it was particularly useful in cable huts, for if one wire was fused the remaining ones were available. It also had the advantage (like Dr. Lodge's) over other guards of preventing the surging back from the earth, by the cable being entirely cut off from the earth at the moment when such surging back would tend to take place. He agreed with Dr. Lodge as to the uncertainty which must surround unexplained faults in cables, and thought that the best protection obtainable should be employed.

Captain STIFFE said that on the Persian Gulf cable he had used a protector consisting of a Siemens plate-guard and a fine platinum wire. Sometimes the wire was melted and the plates had been fused together, but no damage had resulted to the instruments or cable. Before the fine wire was introduced it was not uncommon to have the land-line instruments damaged.

Sir HENRY MANCE corroborated Captain Stiffe's statements, and said that since the Persian Gulf cable came under his charge he had modified the guard by winding the fine wire into a spiral, and enclosing it in a glass tube to prevent mechanical injury. This, he thought, in combination with the plate-guard, somewhat resembled Dr. Lodge's arrangement of an air gap, followed by a coil having self-induction. He admitted that obscure faults do sometimes occur, but did not think they were due to lightning. Siemens' plate guards were fairly efficient, for the plates were rarely fused together ; more frequently their surfaces were merely pitted by the discharge. In conclusion, he asked Dr. Lodge whether the spiral connections from the land lines to the cable and the coiled ends of the cable would tend to protect by virtue of their self-induction.

Major CARDEW thought Dr. Lodge's apparatus was not necessary for ordinary lines. Speaking of the experiments shown at the previous meeting, he pointed out that the unprotected terminals were always struck ; whereas in practice it was possible that the protected terminals might receive the discharge. If, as Dr. Lodge supposed, the line was struck outside the station, then, even at a comparatively short distance away, the impedance of the line would exceed that of Dr. Lodge's coils, and a kind of spark gap exist at each insulator. The successive spans and insulators would thus act as the coils and spark gaps in Dr. Lodge's apparatus.

Prof. HUGHES considered the communication under discussion very important, inasmuch as it recognises the value of impedance in lightning protectors. Many of the older protectors contained analogous arrangements, but their inventors failed to see their importance. Breguet's protector, for example, consists of fine insulated iron wire wound on a brass tube, and surrounded by another tube, both tubes being earthed. Each convolution of wire possesses self-induction, and the insulation acts as a spark gap, so that in effect the protector consists of a very large number of spark gaps in parallel and impedance coils in series. Referring to the cause of the galvanometer kicks about which Dr. Lodge had quoted his opinion, he said that the effect was due to a complicated series of actions ; and although he agreed with Dr. Lodge's notions on the subject, he still thought the main cause thermo-electric.

General WEBBER said one of the advantages of such Papers as the one before them was that they called forth such valuable records of practical experience as those presented by Mr. Preece and Mr. Saunders. No one, excepting Major Cardew casually, had referred to the fact that in ordinary telegraph lines points of release occur at every insulator ; from his own observations on storms in the eastern counties between 1870 and 1874, he was inclined to think that more protection of the offices was due to this cause than to any other. As regards electric light circuits he inquired whether bare or covered underground conductors were most likely to be damaged by lightning. Overhead wires, he believed, were much more likely to be injured than underground ones. Some time ago in his own house, which was then lighted by 25 volt lamps, he noticed, or thought he noticed, the lamps go dark immediately after a vivid lightning flash, and again regain incandescence. The effect he attributed to some inductive state of the earth at the moment of the flash, for an arc lamp in the vicinity was destroyed by the same discharge.

Prof. AYRTON pointed out that the lightning protectors of Mr. Preece and Mr. Saunders could not be applied to electric light circuits ; for it was admitted that plate protectors were insufficient, and the fine wire, an essential part of the arrangements, was inadmissable on account of the strong currents employed. Speaking of damage to telegraphic apparatus, he said he had known polarised relays to be frequently reversed by lightning. In one instance he saw a flash strike a line about a quarter of a mile from the station; every insulator between the point struck, and the station was smashed, the relays fused, and all the instruments damaged, although there was a plate-protector on the line in the office. This, in his opinion, showed that the self-induction of the spans, and the points of release at the posts referred to by Major Cardew and General Webber were insufficient protectors.

Mr. MORDEY said that it was not so much the lightning that was to be feared in electric light circuits, as the current from the dynamo following the path of the discharge, and forming an arc. Means must be devised for breaking up such arcs, and it was more in this direction that electric light engineers were working. Electro-magnetic cut-outs actuated by the currents forming the arcs had been tried for this purpose, and Prof. Elihu Thomson's device for blowing out the arc by a magnet energised by the arc current was in actual use in America.

Mr. SPAGNOLETTI recalled an instance of lightning striking an aerial line, and completely demolishing all the insulators and arms on ten poles, as well as splitting the poles themselves into fragments. In another case a man was killed at Shrewsbury by a flash that struck the line 50 miles away; and on the Metropolitan line he had known an instrument in the centre of a tunnel to be fused, although all the wires connected with it were underground. These cases seemed to show that the protection afforded at the poles referred to by Major Cardew and General Webber to be quite insufficient.

Mr. CROMPTON made inquiries as to how electric light circuits were to be protected, and wished to know if it was necessary to put protectors in each house, or whether protectors at both ends of the leads would be sufficient.

Dr. LODGE said that judging from the statements of several of the speakers the ordinary protectors did their work well, but they were all

Digitized by Google

open to the objection that they were frequently damaged. Whenever protectors were damaged, he contended that something else had also been damaged, although the injury might not be visible. He could hardly accept the statements made by men of experience that they never came across faults that could not be accounted for, and he maintained that any unexplained fault *may* be due to lightning. Even a fraction of 3,000 volts, corresponding to a millimetre spark, might seriously injure a cable. As regards the advantages of fine wire, its use was essential to complete safety. In his Paper he had pointed out that two things had to be guarded against, viz., high potentials and strong currents. His apparatus reduced the high potential, and fine wire was a protection against strong currents. As pointed out by Sir W. Thomson, the fine wire should be at the protected terminals. In reply to Mr. Preece's statement that the self-induction of instruments was sufficient to cause the spark to jump across air spaces, he said that if the coils were wound on iron cores or metal reels, the self-induction for flashes was negligible, and in any case lightning would take no notice of silk or cotton insulation. Moreover, self-induction alone, without supplementary air-gaps, was not sufficient. Corkscrew bits of wire used for convexion had also been appealed to, but the shapes of these coils were by no means such as would give maximum self-induction. He thought Sir W. Thomson's suggestion concerning the fine wire and a condenser might account for some instances of present protection. Referring to Breguet's protector, mentioned by Prof. Hughes, he pointed out that the self-induction of the silk-covered wire was non-existent for lightning flashes. Self-induction, as such, was not the essence of his own apparatus, for an efficient protector requires successive spark-gaps with self-induction between them. In reply to Major Cardew, he said that in his experiments he had imitated the circumstances most likely to occur. As to the relative danger to underground and overhead wires he pointed out that the former were not entirely underground; if they were they would be secure. Covered underground conductors would be more likely to be injured than bare ones, for the insulation of the former might be punctured, whilst the latter could only be damaged by fusion, and this was not likely to occur. He suggested that the lamp phenomenon observed by General Webber might be due to a momentary short-circuiting of the leads by induction from the lightning flash, for he himself once had his storage battery leads short-circuited by resonance sparks caused by discharges in his experiments on lightning conductors. In answer to Mr. Crompton's inquiry Dr. Lodge thought the same principle as is used in protecting buildings from fire by means of fireproof doors should be adopted, and protectors should be placed wherever underground wires leave the earth.

LEGAL INTELLIGENCE.

King, Brown, and Co. v. The Anglo-American Brush Electric Light Corporation.

The reclaiming note by the Anglo-American Brush Electric Light Corporation (Limited)—now known as the Brush Electrical Engineering Company—against the interlocutor of Lord Trayner in the action against them at the instance of King, Brown, and Co., Edinburgh, for the reduction of their patent for series-shunt-wound dynamo machines, came before the First Division of the Court of Session on Wednesday last, the Judges on the Bench being the Lord President and Lords Adam and McLaren. The Lord Ordinary reduced the patent as craved, and found the defenders liable in expenses, holding that the defenders' commutator claim was invalid in respect that the invention claimed in the final specification was larger and different from that claimed in the provisional specification, and that the series-shunt machine was used and publicly known prior to the date of the defenders' letters patent (1878), their machine having been anticipated by the publication of Varley's specification in 1876, and by the use of a machine made according to Varley's specification.

The reclaimers were represented by the Dean of Faculty, Q.C., and Mr. Jameson, instructed by Mackenzie, Innes, and Logan, W.S.; and the respondents by Mr. Graham Murray, Mr. Dickson, and Mr. Daniells, instructed by Davidson and Syme, W.S.

Mr. JAMESON, for the reclaimers, said this was an action of reduction of Brush's patent—a patent which was taken out originally in America, but which was brought here by a communication from America, and was patented by a patent agent of the name of Haddan. It was, therefore, called Haddan's patent throughout the evidence; but perhaps it would be convenient for him to refer to it as Brush's patent. The action of reduction was brought in consequence of an action of putting to silence that was brought by King, Brown, and Co., in consequence of what then were threats administered to them by the Brush Company, for having manufactured compound-wound or series-shunt machines. That action came before their Lordships, and there was a question whether it should proceed first or follow an action brought by the Brush Company against the Orient Company. It was suggested that King, Brown, and Co. should try the question by means of a reduction. Following that suggestion that reduction was brought. There were a number of grounds of reduction set forth in the record, but the grounds which were now founded upon by the pursuers resolved themselves into two or three. They saw, in the first place, in regard to the commutators of that machine, that they were neither original nor useful. He did not know exactly how far the pursuers were going to maintain all their pleas; but he was attacking the Lord Ordinary's interlocutor upon the three grounds which he took up, and in his speech he would only deal with these three points. These points were—first, that with regard to the commutators of Brush's patent, in the completed specification there was something set forth that was not sufficiently shadowed forth in the provisional specification. That was the point against them with regard to the commutators. Then with regard to the main part of the machine, the Lord Ordinary held that that discovery was anticipated by the publication of the patent of Varley in 1876; and the third ground was that the invention was publicly used by that machine of Varley prior to the patent. Brush's patent, as regarded this country, was taken out in 1878, while Varley's was taken out in 1876; but there was this remarkable difference between them, that whereas Brush's patent had been practically used ever since, and hundreds of machines made in accordance with it, Varley's patent had never been heard of until the single machine made in accordance with it was disinterred from a lot of rubbish in the shop of the persons who made it, and brought forward in a previous action—an action which was settled by the parties paying the Brush Company a royalty.

Counsel then proceeded to explain the elementary principles underlying the dynamo. With regard to the commutator he did not know what the other side were going to maintain.

Mr. GRAHAM MURRAY said he was going to maintain that not only was the commutator patent bad in respect of inconsistency between the completed and the provisional specifications, but that it was also bad in respect of prior use.

Mr. JAMESON said the Lord Ordinary was against his friend upon the latter point. His Lordship thought their commutator new and meritorious. They by no means claimed the commutator as a new electrical invention, but that it was a patent on purely mechanical grounds. Returning to the subject of dynamo design counsel said that the question which occurred after Faraday's discovery was how were these armature coils to be kept in an electrical state; and the first and earliest way was to have permanent steel magnets. Then it was found that electro-magnets were very much more powerful than ordinary permanent magnets. These electro-magnets were energised by a voltaic battery, or by a small machine. In short, they got their magnetism for their machine from an independent external source. Then it struck some proficients that they might get the electricity for the magnets from the machine itself. That might be done by having a number of bobbins upon the armature devoted to that work alone. Then a very good idea struck some electricians—he thought there were three people who brought it out at once—and that was known as a series-wound dynamo.

Counsel then briefly described the series dynamo, and referred to the objections which existed in connection with it. Then he described the shunt dynamo, in regard to which he said a communication was read to the Royal Society by Sir Charles Wheatstone. In a shunt machine the current from the armature was split at a terminal, and led into two paths—one of low resistance and the other of greater resistance, called the shunt wire. The objection to the shunt machine was that if you had the useful work of the machine increased in the parallel system you had great loss of magnetism in the magnets. It was in order to provide against this fault that Mr. Brush set himself to invent his machine. He would read what Mr. Brush said about his object in doing so. Mr. Brush said:—"The object of my invention was the production of a dynamo-electric machine that would automatically maintain a substantially or sufficiently constant potential under varying amounts of work in its external or working circuit. In other words, a dynamo that would be adapted automatically to operate normally a small quantity of work as well as a large quantity in its external circuit." The way he accomplished that object of automatic regulation was by combining the series and shunt principles together—by winding the magnets both with a series wire and with a shunt wire, so that in that way they got rid of the specific objections to either form of winding separately used. In a series-shunt machine the series wire current went to the electric light, came back to the machine, went round the magnets, and returned again into the armature. In the same way the current was bifurcated, and went by the shunt wire, travelled round the magnets, and returned to the armature. A great deal was said in the evidence about constant potential. It had been suggested that Brush did not appreciate constant potential. There was no doubt that constant potential had become of more importance since incandescent lighting came into vogue. Brush pointed out, and all the witnesses admitted, that his machine was an endeavour towards automatic regulation of a dynamo, and of course that led to the perfection of the means of attaining constant potential. Although constant potential was not precisely the object he was aiming at—it was automatic regulation he wished to attain—it was proved he practically attained a very near approximation of constant potential.

LORD McLAREN: Is constant potential produced, in consequence of the series-shunt arrangement, always exciting the magnets uniformly?

Mr. JAMESON: No, proportionately to the work done. Continuing, he said he had now sufficiently described the general characteristics of these machines, and he would now proceed to point out the features of the Brush machine. Having shown the machine to the Bench, Mr. Jameson drew attention more particularly to the commutator. There was, first, an insulating hub made of wood, or some other insulating material: the wires were brought into it, and were brought up through little holes into electrical connection with the brass sub-segments, and through these were passed what were called detachably-attached segments of copper in electrical connection again with the brass. These were screwed on by screws of a peculiar construction. They were screws which had more head than tail, and the head was a large, long head which went down through this segment, and the tail was screwed into a brass sub-segment beneath. The great advantage of the arrangement was this, that when this was worn away by constant friction with the brush, they could, without disturbing the electrical connection, just unscrew this copper segment, take it off, and put a new one in its place. That was one of the great advantages of the Brush invention.

LORD ADAM: That does not seem anything very marvellous.

Mr. JAMESON explained that it was a very convenient arrangement. The thing could be unscrewed with the greatest ease without being prised off with hammers and chisels.

Digitized by Google

LORD McLAREN: You just put a new surface on it.

Mr. JAMESON replied in the affirmative. He now went to the provisional specification of Haddan's patent, No. 2,003, of 1878. According to the specification that invention consisted in the construction and use of annular metal armatures grooved on their peripheries or sides or both, and insulated partly or entirely from each other; also in constructing commutators cylindrical to an insulating hub or body, to which were attached metallic sub-segments placed in electrical connection with the general mechanism in which the commutator was employed, and metallic wearing segments detachably attached to said sub-segments. He submitted that this was a sufficient general description of the commutators of this machine. They were cylindrical, and there was an arrangement tending to preserve their cylindricity in this, that they had got screws of a peculiar kind—that they had got an arrangement, without taking off the copper segments, so as to have the cylindricity of this constantly preserved, with an insulating hub or body that was obtained by means of large wires which were insulated from each other, and also insulated from the shaft, "to which are attached metallic sub-segments." These were segments placed in electrical connection with the general mechanism in which the commutator was employed. "Metallic wearing segments detachably attached to the sub-segments." These were attached in such a manner that they could be easily detached from each other by means of the screws. Dealing next with the final specification, Mr. Jameson referred their Lordships to p. 16, which set forth the following description: 1. An annular armature consisting of two or more plates formed with grooved sides or peripheries, or both, and insulated entirely from each other, substantially as shown in division No. 2. 2. A commutator cylinder, consisting of an insulating hub or body, to which are attached sub-segments placed in proper electrical connection with the general mechanism in which the commutator is employed, and wearing segments detachably attached to said sub-segments, substantially as shown in division 3. 3. The combination of sub-segments R, wearing segments S or T, screws K, substantially as and for the purposes shown in division 3. 4. The commutator having metallic insulating segments T, substantially as shown in division 3. 5. A commutator, having metallic insulating segments T, attached to and forming part of the adjoining conducting segments S, substantially as shown in division 3. 6 A commutator having two conducting segments, S, two opposing ends of which said segments are separated by an intervening insulator, T; the other ends of said segments, while insulated from each other, being closely associated, and not provided with an insulator T, substantially as shown in division 3. The criticism made upon No. 2 was that it exceeded the whole of the provisional specification. In one sense it did so. The patentee gave a general description of the commutator, and then, as he must take every part of his invention in order that he might not be cut out by some person subsequently claiming part of it and omitting the rest, or claiming part of it and adding something to it, the patentee then went on to No. 6, to complete his claim under this head. He (Mr. Jameson) submitted that all these matters were properly and sufficiently foreshadowed in the provisional specification. No. 2 was a general description; No. 3 was a combination of the three parts of what made up the commutator; No. 4 was, again, just a single integer of the combination, viz., the insulating segment T; No. 5 was an attachment to the insulating segment T, so as to make it a conducting as well as an insulating segment. Now, keeping in view that this invention was merely one of mechanical details, and not of any electrical principle, this was a description of a particular commutator.

LORD McLAREN: How is this an insulating segment?

Mr. JAMESON: It comes between two segments which were in electrical connection with the bobbins, and had the effect of cutting the bobbin out at that particular point.

LORD McLAREN: So far as regards the bobbins the part of the armature that was previously at work is no longer insulated from the next one?

Mr. JAMESON: It might be entirely detached, in which case the only use of it would be to keep up the cylindrical form without having any detachment whatever. It did good in this way—that it presented a larger surface to the brush. It made a larger surface between the brush and that wire which was in connection with the electric current. It was insulated with reference to the segments on either side, but it did not insulate with reference to segments to which it was attached. He did not say that it had great electrical advantages, but it tended to make the machine special. Two rounds of copper connected with each other conduced to the rigidity of the whole commutator. Now, it was said that was not properly foreshadowed; and Lord Trayner had adopted that view. Well, first as regarded the commutator, Mr. Brush described his invention in the provisional specification in these terms: "In constructing commutators, cylindrical, with an insulating hub or body, to which are attached metallic sub-segments placed in electrical connection with two wires, with the general mechanism with which the commutator is employed, and wearing segments detachably attached to said sub-segments." He held there was nothing uncommon in a patentee claiming not only the combination of a great number of details, but also claiming one of these details by itself as a separate and independent claim; and if this was set forth in the provisional specification, the machine, described as a whole, did not put aside what he claimed for particular parts. He might claim any part of it whole, or any integer, or any combination of two or more integers of the whole, with the view of preventing his patent being infringed. Lord Trayner seems to have said that in the provisional specification they must not only generally describe the invention, which he understood was all that was required; but it must be done sufficiently to allow the invention to be known. The provisional specification was in order to secure a patentee's invention, and then he got six months to perfect it, and give a final specification. It was time given to him to perfect his invention and work out the details, and in working out the details he would find out what his invention was worth, and would put in a claim for the patent, not only as a whole, but also for parts of his invention.

LORD McLAREN: The thing Lord Trayner holds against seems to be an important part of the final specification. It occurs to me that the process in this case might be suited to allow the Brush Company to disclaim this part, as was done in the case of Sir William Thomson.

The LORD PRESIDENT: Is not that too late now?

Mr. MURRAY: In Sir William Thomson's case the disclaimer was made before the judgment. It is a very arguable point whether it could be done now.

The LORD PRESIDENT: There is a good deal disclaimed already.

Mr. JAMESON: A good deal, my Lord. The whole of the shunt arrangement was disclaimed because, at the date of this patent, Mr. Brush did not know it had been patented at all. It turned out that something approaching shunt had been foreshadowed by Sir Charles Wheatstone in a communication to the Royal Society.

LORD McLAREN: He now claims the shunt and series as what is known as compound winding.

Mr. JAMESON: That is so.

The hearing was adjourned till yesterday (Thursday).

Watt v. Maxim-Weston Electric Light.

This was an appeal from Mr. Justice North refusing to order a counter-claim by the defendant company to be struck out, which came before the Appeal Court, consisting of Lords Justices Cotton, Lindley, and Bowen, on Friday last.

Mr. Higgins, Q.C., and Mr. G. F. Hart, instructed by Messrs. Michael Abrahams and Son, appeared for the appellant; Mr. Cozens-Hardy, Q.C., and Mr. Gazdar for the respondents.

This action was brought by Mr. Hugh Watt, late managing director of the Company, for a number of liquidated demands, such as arrears of salary, rent of offices, &c., and also for damages in respect of certain shares, transfers of which the Company declined to register. He originally claimed a mandatory order directing transfers to be registered; but on the Company going into voluntary liquidation for purposes of reconstruction, this claim was changed into one for damages. Mr. Watt and others dissented from the reconstruction scheme, thereupon they were entitled to have the value of their interest ascertained, but an agreement was come to that the value of the shares should be taken at 1s. 6d. In Mr. Watt's case, however, there was a further dispute as to the number of shares to which he was beneficially entitled, and that question was referred to the arbitration of Mr. Frederick Whinney. The plaintiff claimed to be entitled to 7,376 shares; but Mr. Whinney, by his award, declared him entitled to 4,416, and to a further number of 2,710 if he paid up 5s. a share upon them to the Company. The counter-claim was for the calls on these shares; and the appellant sought to have it struck out on a variety of grounds, but mainly because, as he alleged, it was frivolous and vexatious, and disclosed no ground of action. There was also a technical ground, that it had been introduced without leave, but that Mr. Justice North had dealt with, by giving leave at the time of the application before him.

Their Lordships, without calling upon Mr. Cozens-Hardy, dismissed the appeal, Lord Justice LINDLEY saying that it was one which ought never to have been brought.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 15, 1890.

Meeting of the American Institute of Electrical Engineers.—The meeting of the American Institute of Electrical Engineers, to be held in Boston next week, promises to be of unusual interest. It will be held at the Massachusetts Institute of Technology, and bids fair to be attended by a large proportion of the well-known electricians in this section of the country. The Papers promised are of importance, and one of them is likely to throw a good deal of light on the much-talked-of question of high-speed electrical traction. It is to be read by Mr. O. T. Crosby, chief engineer of the Weems electric railway system, and his subject is "The Limitations of Steam and Electrical Transportation." The author has worked out this problem with great care, and has the invaluable resources of an unusually large practical experience. The Paper is one which will command attention from electricians interested in electrical traction. There will also be some valuable experimental demonstrations of the capacities of the automatic electric welding machines, by Mr. Lemp, well-known by his connection with the Thomson-Houston Company. From year to year these meetings of the Institute grow to be of more importance and value.

The Wenstrom Dynamo.—A very vigorous effort is being made to push the Wenstrom dynamos and motors in this country. A company, with a capital of a million dollars, has been organised in Baltimore for the purpose of manufacturing these machines, and a well-known firm of electrical engineers has taken the agency for them and proposes to push the business in the most vigorous manner. The Wenstrom is comparatively

Digitized by Google

little known at present in this country, but its reputation is good, and the tests that have been made have been of a very satisfactory character.

The Duncan Slow-speed Motor.—A new slow-speed motor has just been patented by Dr. Louis Duncan, of Johns-Hopkins University, of Baltimore. It is a multipolar machine, with revolving field-magnets, and the arrangement of the poles and armature is such as will unquestionably give a very powerful torque and a considerable degree of efficiency. It is rumoured that the machine is to be for very low speeds, and, from its form, and this valuable characteristic, it may prove no inconsiderable factor in electrical traction business in the future. It is too early to speak more in detail. The machine seems to be distinctly a meritorious one.

Rapid Transit in New York.—The hopes of New Yorkers for rapid transit are rather nipped in the bud by the inefficiency of the New York Legislature in dealing with the subject. It was hoped that, for the sake of the long-suffering public, a franchise would be granted that would enable us to have electric or cable roads, or both, within a short time. The travelling facilities in the city are entirely inadequate at present to the needs of the time, and there is a strong movement towards doing something effective without further delay. The Real Estate Exchange of this city, realising how important the subject is to the growth and development of the outlying districts of Manhattan Island, have addressed vigorous remarks to Governor Hill on the subject, and it is to be hoped that some good result will come therefrom.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *May* 24, 1890.

The installation at the Gare de l'Est, to which I briefly alluded in a previous letter, is of a very complete character. The generating plant is situated in the Faubourg St. Martin, and the station is arranged on the American principle, that is to say, the steam engines and dynamos are placed on the ground floor, the switchboards on the first floor and boilers on the second floor. The boilers are of the Bellville type, the steam engines of the Weyher and Richmond type, and the 3100 kilowatt dynamos are of the Manchester pattern, made by the firm of Sautter-Lemonier, who undertook the whole of this installation. The distribution is carried out on the three-wire system at a pressure of 70 volts, and comprises 130 arc lamps, taking 850 amperes and 1,500 incandescent lamps, requiring a current of 1,180 amperes. The dynamos are direct belt-driven, and run at 300 revolutions. At this speed, with an exciting current of thirty amperes, each machine generates 1,200 amperes at a pressure of eighty volts. As a rule, two machines only are used, but the third is kept running slowly in case of a breakdown. As only one machine is kept running in the daytime, two of the three mains are joined together.

Up to the present the use of alternating currents seems likely to hold its own against continuous currents for the lighting of La Belle Jardinière, which I mentioned in my last letter. The struggle, however, is not over yet, and there is still room for hope that the municipal authorities will not make the mistake of establishing a special circuit with a pressure of 2,400 volts, in order to supply light to a customer only a quarter of a mile away from the municipal station, from which a distribution at 200 volts is already in operation.

In his recent address to the Société Internationale des Électriciens, M. Hippolyte Fontaine gives some interesting figures with regard to the electric light in Paris. At the present moment there are 6,800 arc lamps and 118,000 incandescent lamps in use in this city. In 1877 the electric light was represented by 65 *bougies-décimales* hours per inhabitant, in 1883 by 230, and in 1889 by 2,130. According to M. Fontaine gas furnishes 57·3 per cent., and electricity 18·9 per cent. of the total light of Paris.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *May* 24, 1890.

Mr. Edison is expected to visit Vienna shortly, and great preparations are being made by the Vienna Electro-Technical Society to give him a fitting reception.

It is an ill wind that blows nobody any good. The riots in Biale, and the fear of riots on May 1st, opened many an official eye to the great value of telephonic communication. In Biale nearly the whole of the arrangements for protecting the twin towns of Bielig and Biale were done by telephone. Two new lines had to be put up for the town authorities, and one for the commander of the troops. At a banquet given by the town to the officers, it was acknowledged that without the telephone the service of protecting the town could not have been carried on as well as it was. In all other towns the police and town authorities felt the necessity of increased telephonic communication, especially in Vienna; and the result has been that many a new exchange subscription was contracted. So much was thought of the value of uninterrupted telephonic communication that the long pole routes in some of the towns were watched by cavalry patrols.

The Austrian Government have opened a large number of small exchanges during 1888 and 1889; and up to December 31, 1889, the totals were 62 call offices and 662 subscribers. The following trunk lines have also been opened by the Austrian Government:—Vienna to Brünn (Van Rysselberghe); Vienna to Prague (separate line); Vienna to Budapest (three wires); Vienna to Reichenau; Vienna to Baden; Vienna to Vöslau; Vienna to Wiener-Neustadt; Vienna to Neunkirchen; Vienna to Mödling; Aussig to Brüx; Aussig to Karbitz; Aussig to Mariaschein; Aussig to Teplitz; Aussig to Dux. This year the Government intend running the lines between Prague and Pilsen; Prague and Aussig and Tiplitz; Reichenberg and Gablonz; and Reichberg and Friedland. Next year they propose running a line from Vienna to Trieste, another from Vienna to Graz, and also a new separate line from Vienna to Brünn, to supersede the present Van Rysselberghe line, and finally a line from Prague to Brünn.

The Karlsbad Town Council have voted the sums necessary for the electric lighting of the town. Messrs. Ganz and Co.'s plans have been accepted, and the work is to be completed before the next season begins. Zizkor, a suburb of Prague, has now been lit up for some time by the electric light. The dynamos and electrical apparatus were supplied by Messrs. Krizik. Mr. Krizik's name is not much known in England, though his lamps are well known under the name of the Pilsen-Joel lamp, Pilsen being Mr. Krizik's home at the time. Mr. Krizik has applied for a concession to connect the lovely Belvedere gardens in Prague with the Baumgarten Park by an electric railway. In Brünn a company is being formed for central-station lighting, with the help of that enterprising and ubiquitous firm, Messrs. Ganz and Co., of Budapest. The Vienna Houses of Parliament are also lit by electric light, the installations having been carried out by Messrs. Siemens and Halske. The hall of the Commons is lit up by 25 400 candle-power, and 60 16 candle-power glow lamps. The Budget Commission Room is lit by two fine lustres, each with 30 16 candle-power lamps. The hall of the Upper House is lit in the same way as the Lower House, but being smaller, with only 20 400 candle-power lamps.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Public Libraries Committee of Newcastle-on-Tyne invite tenders for (1) providing and fixing all lamps, wires, and fittings for an installation of the electric light at the Public Library in New Bridge-street; (2) supply of electric energy for the working of lamps, &c., for a minimum average of eight units per hour during the lighting season. Specifications and plans may be inspected and forms of tender obtained at the City Engineer's office, Town Hall, on and after June 5th. Tenders, addressed to the Chairman of the Public Libraries Committee, must be in by June 19th. Further particulars are given in our advertisement pages.

SALE BY AUCTION.—We call our readers' attention to the sale by auction, on Tuesday and Wednesday next, of the electric plant, stock of machinery, utensils, &c., of the Schmidt Douglas Electric Works, Bradford. Catalogues are now ready, and the plant will be on view on Monday next and on the mornings of sale. Further particulars are given on page xiii. of our advertisements, and full information can be obtained of Mr. Edgar Musgrave, 1, Bank-street, Bradford; Mr. Thomas England, Town Hall-chambers, Halifax; or of the auctioneer, Mr. Wooller Jennings, 43, Old-market, Bradford.

PERSONAL.—Mr. Walter F. Jones, late representative of Messrs. Felten and Guilleaume, cable manufacturers, has joined the staff of Messrs. J. B. F. Andrews and Co., of 41, Parliament-street. Mr. Jones was previously with Messrs. Andrews in Glasgow.

ELECTRICAL ENGINEERING COMPANY of IRELAND.—This Company have taken large premises at 61, Dawson-street, Dublin, where they will carry on the business of electrical engineers. The position is advantageously adapted as a centre for electric lighting, several contracts for which the Company are at present carrying out.

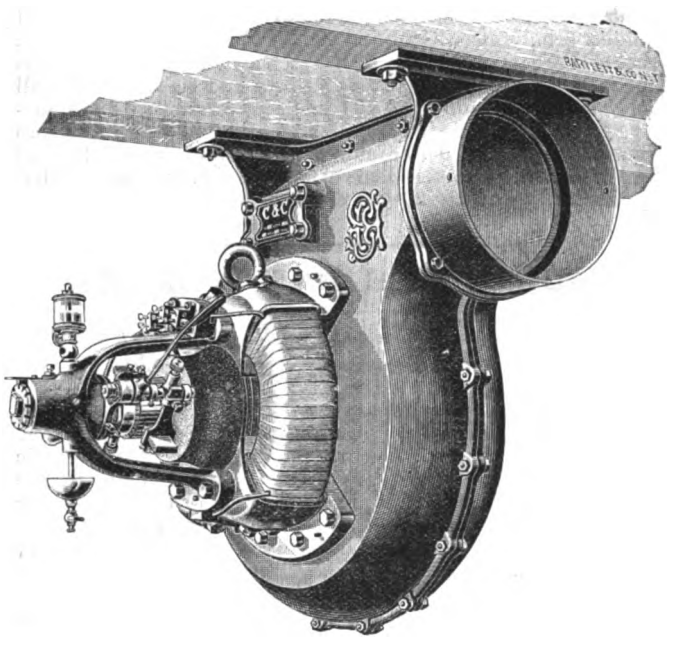
MESSRS. NALDER BROTHERS AND CO.—We have received this week the new (3rd) edition of the catalogue issued by this firm. It is very fully illustrated, and gives concise particulars, together with prices, of the well-known electrical instruments manufactured by them. The illustrations and descriptions include batteries and standard cells, condensers, electrometers, galvanometers, keys, ammeters, and voltmeters, secohmmeters, Ayrton and Perry's standard of self-induction, pocket micrometers, Newall's sensitometer, Prof. S. P. Thompson's new standard spherometer, resistance coils, the Poggendorff motor bridge, a portable testing set, &c., &c. The catalogue concludes with a number of illustrations and descriptions of electrical apparatus and instruments of which Messrs. Nalder Brothers are the manufacturers, specially selected from Prof. Ayrton's work on "Practical Electricity."

HERR G. WEHR, BERLIN.—We are in receipt of some admirably illustrated catalogues of electrical instruments and apparatus manufactured by this firm, in which illustrations, particulars and prices are given of telephones, microphones, electric bells, annunciators, switches, switch-boards, insulators, batteries, galvanometers, lightning conductors, and all kinds of apparatus connected with electric lighting, telegraphy, and telephony.

AN ELECTRIC BLOWER.

Proper ventilation is an important desideratum in modern vessels, and it is especially needful in the engine rooms, galleys, and those portions of the ship occupied by the crew. As shafting and belting are in most cases out of the question on board ship, the use of electricity as a motive power for driving ventilating fans has become very general. An electric blower can be put up anywhere, as the wire carrying the current can be easily run, and this application of the electric current provides a most convenient and in some cases the only means of renovating the air. The orifice of discharge in a blower is smaller in proportion to the amount of air passing through than that of any other machine for creating a forced draught of air; and this specially recommends it for ships



and in places where the discharged current of air has to be carried a distance in pipes, as the pipes required are small and no special provision need be made beforehand to allow space for them. The accompanying illustration is from a photograph of one of the "C and C" Electric Motor Company's electric blowers placed on the United States cruiser "Baltimore." It discharges 1,425 cubic feet of air per minute. Fastened to the ceiling of the dynamo-room, it completely changes the air of the room once every two minutes, discharging it at a distant point through a small pipe. The machine is very compact, and does its work so noiselessly that a person standing near cannot tell without the closest observation whether it is running or not. The ease with which electric blowers can be set up and connected to the dynamos, without requiring any shafting, belting or other contrivance except a small wire, has naturally brought them to the attention of shipbuilders.

Messrs. Shippey Brothers (Limited), of King-street, Cheapside, E.C., are the agents in this country for the "C & C" Company's manufactures.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.

April 19, 1890.

5,942. H. C. L. HOLDON. London. Improvements in the construction of electrical vent-sealing tubes for firing ordnance and like purposes.

April 21, 1890.

5,996. W. B. SAYERS. Putney. Improvements in electric incandescent lamps.

6,000. W. H. SCOTT, and LAURENCE, PARIS and SCOTT (Limited), Norwich. A new and improved method of making house or other connections with or without fuses to underground electric mains.

6,005. G. H. SAYER. London. Electric lamp adjuster.

6,032. M. W. DEWEY. London. Improvements in electric heating apparatus.

6,037. M. W. DEWEY. London. Improvements in and relating to electric railway vehicles.

April 22, 1890.

6,041. M. W. DEWEY. London. Improvements relating to the transformation and utilization of electrical energy.

6,082. J. E. WALLER and E. MANVILLE. London. Improvements in the means of and apparatus for distributing and collecting electricity for the propulsion of vehicles.

6,083. J. GORDON. London. Improvements in effecting the electric propulsion of tramcars and apparatus therefor.

6,100. J. SCOTT and F. E. DAVIS. London. Improvements in electric machines for covering wire.

6,120. C. J. KINTNER. London. Improvements in and relating to systems of electrical distribution.

6,124. J. F. MUNSIE. London. Improvements in manholes for underground electric circuits.

6,125. J. F. MUNSIE. London. Improvements in and relating to underground main and branch conduits for electrical conductors, and to feeding devices therefor.

6,126. R. D. RADCLIFFE. London. Improvements in electrical signalling apparatus for police service, and the like.

6,138. S. CLARKE. London. Improvements in screens or shades for lamps and gas or electric lights.

April 23, 1890.

6,156. G. SCHULTZ. London. An improved electrical switch for the better and more safe means of breaking the continuity of an electric circuit of high voltage, and again establishing the same.

April 24, 1890.

6,266. J. MARX. London. Improvements in means for use in electrolysis.

6,267. J. MARX. London. Improvements in means for connecting electrical conductors, applicable more especially for connecting conducting-wires or strips to electrodes used in electrolysis, and as a safety device for electrical purposes.

April 25, 1890.

6326. E. BATAULT. London. Improvements in electricity meters. (Date applied for under Patents Act, 1883, Section 103, 28th September, 1889, being date of application in Switzerland.)

April 26, 1890.

6,359. H. J. PEDDIE. Edinburgh. Improvements in the sections and forms of iron rails, in the method of laying them, and placing within them an electric conductor; and in the manner of applying the electric brush of an electric motor to the aforesaid electric conductor for use on electric tramways and railways.

6,372. G. COHEN. Manchester. Improvements in medical induction coils.

6,389. A. BLATTNER, London. An electric motor.

6,392. O. T. BLÁTHY, London. Improvements in safety-fuses for electric currents.

April 28, 1890.

6,475. W. LOWRIE and C. J. HALL. London. A safety device for electric circuits.

6,476. H. T. EAGAR and R. P. MILBURN. London. Improvements in electrical batteries.

6,490. E. SCHWEIZER. London. Electrical clockwork for pendulum timepieces.

6,492. M. W. DEWEY. London. Improvements in electric railways. [Date applied for under Patents Act, 1883, Sec. 103, November 2, 1889, being date of application in United States.]

6,493. M. W. DEWEY. London. Method of electric refrigeration. [Date applied for under Patents Act, 1883, Sec. 103, November 15, 1889, being date of application in United States.]

COMPANIES' MEETINGS & REPORTS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The ninth annual ordinary general meeting of this Company was held at the Terminus Hotel, Cannon-street, yesterday. In the unavoidable absence of the Chairman, Mr. C. L. W. Fitzgerald, the chair was occupied by Sir Alexander Armstrong, K.C.B., &c.

The SECRETARY (Mr. Charles Curtoys) having read the notice convening the meeting,

The CHAIRMAN said he was sure, from the report in the hands of the shareholders, that they would consider that the affairs of the Company were in a very satisfactory state. They would perceive that the accounts showed a net profit of £12,714. 5s. 8d., which, with the amount carried forward from last year, left a balance of £14,272. 18s. for disposal, after making provision for doubtful debts. The Directors proposed to deal with this amount as follows: namely, to pay a further dividend of £7 per cent. for the half-year on the ordinary shares, and £6 per cent. on the Preference shares, making, with the interim dividend paid in November last, £6 per cent. for the year on both descriptions of shares, writing off the sum of £543. 3s. 8d. for depreciation of plant and machinery and furniture, and the sum of £2,000 for the Edison Gower-Bell Telephone Company's securities, leaving a balance of £1,842. 18s. to carry forward. During the year the Directors had received a further and final payment of £485. 16s. on account of the profit arising from the liquidation of the River Plate business, which concluded the Company's negotiations in that quarter, and which they must regard as a satisfactory settlement. They were aware, no doubt, of the action that was going on in Belgium with regard to the patent rights of the Edison Gower-Bell Company. He was sorry he was not in a position to give them any definite information as to its final issue. He would simply say that all the preliminary decisions had been in their favour—that was to say, in favour of the Edison Gower-Bell Company, with which their own Company was intimately allied. He thought it was not unlikely that a decision would be arrived at before the close of the year—that was to say, before the Long Vacation—for matters were now in such a forward state that the decision could not be long delayed. The subsidiary companies continued to make most satisfactory progress. He found that in Austria there had been an increase of 427 subscribers and of £2,512 rental. With regard to the Anglo-Portuguese Telephone Company there had been an increase of 202 subscribers and of £1,155 rental. They were all aware of the state of affairs in Portugal recently, and of the rather hostile feeling which existed with respect to every enterprise bearing an English name. Under these circumstances it might naturally have been thought that the Company's business would have consequently suffered largely. He was happy to say, however, that such had not been the case. During the year there had been a very steady progressive increase, which must be considered very encouraging under the circumstances. He hoped that when they next met they would have to report a still further steady advance in the business of the Company. With regard to the issue of the 10,000 Preference shares, he ought to mention that they had been taken up very rapidly, applications for considerably over the amount having been received. He looked forward to a still more hopeful future. He concluded by moving the adoption of the report and balance sheet.

Mr. H. GREWING seconded the resolution, which was carried unanimously.

In answer to Dr. HARDIE, Mr. J. G. GRIFFITHS, one of the Company's Auditors, said that the Company became originally interested in the Edison Gower-Bell Company by the acquisition of 174,995 shares in exchange for its patent rights. It subsequently purchased 20,000 Preferred and 15,000 ordinary shares, which were from time to time re-valued by the Directors, in accordance with their appreciation of their value.

The CHAIRMAN next proposed the re-election of the retiring Directors, Mr. C. L. W. Fitzgerald and Mr. Henry Grewing.

Mr. J. H. BUCKINGHAM, in seconding the motion, paid a warm tribute to the ability and painstaking care of both gentlemen in promoting the interests of the Company.

The motion was carried unanimously.

On the motion of the CHAIRMAN, seconded by Dr. HARDIE, Mr. Griffiths was re-appointed an auditor; as was also Mr. A. E. Green, on the motion of Mr. DAINES, seconded by Mr. GARDINER.

The motion was carried unanimously.

Mr. R. E. BATEMAN then proposed a cordial vote of thanks to the Chairman (Sir Alex. Armstrong) for presiding, the Directors, and the secretary; and begged to give expression on behalf of the shareholders to

Digitized by Google

the sincere regret they all felt at the domestic bereavement which caused the absence of their Chairman, Mr. C. L. W. Fitzgerald.

This was carried unanimously.

The following report has been circulated amongst the shareholders:—

The accounts for the year ending the 31st March, 1890, show a net profit of £12,714. 5s. 8d., which, with the amount carried forward from last year, leaves a balance of £14,272. 18s. 0d. for disposal, after making provision for doubtful debts. The Directors propose to deal with this amount as follows, viz.: to pay a further dividend of £7 per cent. for the half-year on the ordinary shares, and £6 per cent. on the Preference shares, making, with the interim dividend paid in November last, £6 per cent. for the year on both descriptions of shares; writing off the sum of £543. 3s. 8d. for depreciation of plant, machinery, and furniture; and the sum of £2,000 from the Edison Gower-Bell Telephone Company's securities, thus leaving a balance of £1,842. 18s. 0d. to carry forward. During the year the Directors have received a further and final payment of £485. 16s. 0d. on account of profit arising from the liquidation of the River Plate business, which is included in the above statement. The Directors having deemed it in the interest of the shareholders that all parts of the telephone possible should be made in the factory, have lately built and fully equipped with machinery of a novel character, two workshops for manufacturing all the woodwork required. This has proved a great success. The action in Belgium, relating to the patents in which the Edison Gower-Bell Telephone Company is interested, is still in the hands of the experts; every effort has been used to hurry the matter on, but almost innumerable obstacles are placed in the way by our opponents.

The subsidiary companies continue to make most satisfactory progress, as is shown by the following statement:—

——	Year ending 31st March.					
	Subscribers.		Rental.		Increase.	
	1889.	1890	1889.	1890.	Subscribers	Rental
			£	£		£
Telephone Company of Austria	2,441	2,868	15,588	18,100	427	2,512
Anglo-Portuguese Telephone Company.....	1,713	1,915	11,077	12,232	202	1,155
Total increase for the year.....					629	3,667

In relation to the subsidiary companies, affairs in Portugal have caused your Board some anxiety, owing to the differences that have arisen between the two Governments. Matters, however, seem to be settling down in that quarter, and it is hoped that no harm will result.

Hastings and St. Leonard's-on-Sea Electric Light Company (Limited).

The annual general meeting of this Company was held on May 21st, at the office, Earl-street, Hastings; Mr. H. M. Baker, J.P., presiding. The notice convening the meeting, and minutes of the last meeting, were read and confirmed.

The annual report, which was taken as read, was as follows:—

"The Directors present herewith their statement of accounts for the year ended March 31, 1890. The revenue from lighting, rentals and fittings for the past year amounts to £2,561. 18s. 5d., as against £2,189 9s. 5d. for the year ended March 31, 1889, or an increase of £372. 9s. 0d. On the other hand, there has been an increase for the past year in wages, fuel, and hire of dynamo of £292. 1s. 0d.; the last item would have been still higher but for the purchase of the dynamo on favourable terms. The net profits, it will be seen, amount to £501. 8s. 1d., from which must be deducted the interest on mortgage and debentures, amounting to £280. 8s. 10d., leaving £220. 19s. 3d., which, added to £81. 11s. 8d. brought forward from last account, makes the sum available for dividend £302. 10s. 11d., out of which the Directors propose to pay a dividend of £3 per cent. free of income-tax, which will amount to £205, leaving a balance of £97. 0s. 11d. to be carried forward to the next account. Application has been made to the Board of Trade for a Provisional Order under the new Electric Lighting Act; and the Corporation, whilst applying also for powers under the same Act, have not opposed the application of the Company; and the Directors consider that it would be to the interest of the ratepayers if the whole of the lighting of the borough were undertaken either by the Company or by the Corporation. Captain Hennah, R.N., having resigned the office of secretary, the Directors have appointed Mr. Francis E. Burton to succeed him. Mr. F. Noakes and Mr. F. J. Parsons retire from the directorate by rotation; they are eligible, and offer themselves for re-election. The auditors, Messrs. Hart Brothers, Tibbetts, and Co., also retire, and offer themselves for re-election."

The CHAIRMAN, in moving the adoption of the report, said he had a communication from Mr. R. Hammond, a gentleman very largely interested in the Company; and as the letter was an important one, he would read it to them. It ran as follows:—"I am in receipt of the report and balance-sheet of your Company for the year ending 31st March, 1890, and, as a shareholder, I must congratulate the Directors upon the management of the business, which has been carried on with so small a plant with a result on the right side. I feel absolutely confident that if a good-sized plant were laid down in Hastings similar to that which has been laid down by the House-to-House Electric Light Company at Kensington, the economy arising from the larger machinery would lead to a very good financial result; and I must congratulate you and your colleagues upon having obtained the sanction of the Board of Trade to a Provisional Order giving your Company Parliamentary powers. I am confident that capitalists will be found ready to subscribe the necessary amount to lay down improved works, you having done so well your pioneer work." The Chairman pointed out that Mr. Hammond was largely interested in the Company, and had often assisted them in the working They would see that since their last meeting their Debentures had increased from £1,000 to £1,500, and these extra Debentures had been taken up by Mr. Hammond. At the time it had been of great assistance to them, and had had more than one beneficial effect. One of the benefits had been that it had enabled them to meet a demand of their bankers with reference to the interest of a mortgage held by them. There was another benefit, and that was that it had enabled them to execute some improvements in their boilers, the carrying out of which would be the means of greatly lesseuing the amount of fuel necessary; and he thought that their next balance-sheet would show a great saving had been effected in this respect. He believed in giving praise where it was due, and he thought that in their engineer they had a very valuable servant. The Chairman mentioned that, during the last year, the engineer had been offered a very lucrative position. He appealed to the Directors for their opinion on the matter, and they let him see that he was unfettered in this respect. After further considering the matter, however, he had decided to remain with them; and the Chairman hoped that the position of the Company would be such in the future that Mr. Mercer would not regret that he had not left. The Chairman then referred with satisfaction to the obtaining of their Provisional Order, by the increased powers granted to them under which he said they would be in a better position than before. He then mentioned the fact that the Town Council had at last arrived at the conviction that it was desirable to light the town by electricity, and expressed himself of opinion that the adoption of the electric light in the town would be a great advantage. With reference to the granting of their Provisional Order, he thought that they owed a great deal to the legal skill which Mr. Langham had exercised in the matter. He then referred to the fact that during the

last eight years the Directors had had much anxious work; and although they had not had remuneration, still they were gratified, and, he might say, satisfied, with the success which the electric light had at last obtained in the town. He considered that at present their Company stood second to none of the provincial Electric Light Companies in the country. Alluding to the resignation of Captain Hennah from the office of secretary, the Chairman said that, like a true captain, he had not left the ship until it was in still waters. He thought that in Mr. Burton they would have a most efficient secretary. He had much pleasure in moving the adoption of the report, and the payment of a dividend of 3 per cent. Amongst the many adverse criticisms which they met with was that they had only declared a dividend on paper, but on that occasion that attack could not be made, for they now had the money, and the dividend would be paid at once.

Mr. BRAGG seconded the adoption of the Report.

Mr. BRAY asked whether the Town Council had been granted any powers by the Local Government Board for the supply of electric light to the town?

Mr. RODDIS said they had not, and he should very much doubt whether they would get it. He thought that if the ratepayers seemed to think that in widening the road along the Front the Council would be carrying out an extravagant work, it would be considered that they were extravagant in borrowing money for starting works for supplying the town with electric light.

Mr. LANGHAM thought that if the Council determined upon carrying out the work they were going to learn by experience, the same as that Company had done for the last eight years. He also considered that it would be very hard on the Company if, after these years of struggle, just as they were in a position to make their work a success, the Council should compete with them. He did not, however, think it would do the Company much harm, for they still had private lighting to depend upon. Mr. Langham pointed to the fact that the Board of Trade had endeavoured to make them reduce the scale of charges, but he had argued that it would not be fair to put this Company on a footing with those whose works were centred in very populous districts, and who supplied a large amount of light in a very small area. Owing to the straggling nature of their area of work they incurred a much larger expense in supplying the light, and by his representation of their position to the Board of Trade it had been decided that they should be allowed to charge the price stated in the Order as the maximum rate. They had now been able, by dint of great economy, to pay a dividend of 3 per cent., and they believed that, with additional capital, they would be able to supply more light with the same plant. They had all but one thing necessary for carrying on an extensive business, and that was the money which was needed to develop it. He thought that they were now in a position to appeal to the public, for theirs was an Electric Light Company which was able to pay a dividend, and he had no doubt that, with increased capital, they would be able to make the affair a great success.

The Report was unanimously adopted; and the retiring Directors (Messrs. Noakes and Parsons), and the auditors (Messrs. Hart Brothers, Tibbetts, and Co.) having been re-elected, the meeting terminated with a vote of thanks to the Chairman.

NEW COMPANIES REGISTERED.

GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED).—Objects: To carry on the business of manufacturers and contractors for the supply of electrical power of all kinds, adopting therefor agreements to be entered into with the Electric Traction Company, Limited, Moritz Immisch and Company, and the Electric Construction Corporation, Limited. The capital of the Company is £350,000, in £10 shares, whereof 10,000 are preference shares, with priority in return of capital to the holders of ordinary shares. Vote per ordinary share, and two votes for each preference share. First Directors (three to seven) to be appointed by subscribers. Qualification, fifty shares. Remuneration, £250 each (chairman £500). Borrowing limit, one-half of subscribed capital. Registered, May 22, by Ashurst, Morris, Crisp, and Co., solicitors, 6, Old Jewry, London.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended May 23rd amounted to £4,617.

THE GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED).—The prospectus of this Company is issued announcing its formation with a capital of £350,000, in 10,000 £7 per Cent. Cumulative Preference shares of £10 each and 25,000 Ordinary shares of £10 each. The Preference shares are entitled, in addition to the cumulative preferential dividend of £7 per cent. per annum, to a contingent rateable division of profits with the Ordinary shares after payment of a non-cumulative dividend of £10 per cent. on the Ordinary shares. They are also entitled to priority in repayment of capital. The amounts payable on the shares are as follows:—10s. on application, £1. 10s. on allotment, £2 on September 1st next, and the balance in amounts of not more than £2 per share at intervals of not less than three months. The Company is established for the purpose of purchasing, amalgamating and developing the well-known businesses of the Electric Traction Company (Limited) and Messrs. Immisch and Co. The prospectus gives full particulars of the principal work recently accomplished or now in hand in these companies, and sets out in detail the various items which form the property of the new Company. This includes, in addition to the businesses already mentioned, a licence from the Electric Construction Corporation to use their patents for electric traction throughout the United Kingdom, and a contract upon the most favourable terms for the supply of their traction accumulators. Details are given in the prospectus of the electric launches fitted out by Messrs. Immisch upon the Thames, and also of those of the Traction Company running on the Union Canal for the visitors to the Edinburgh Exhibition, and also sets out a large number of mining and colliery plants laid down by Messrs. Immisch and Co. Of the capital issued, the whole of the Preference shares will be applied solely to the development of the business of the present Company. The full prospectus is set out on p. xiv. of our advertisements; and prospectuses, with forms of application for shares, may be obtained at the offices of the Company, 35, New Broad-street, E.C.; of the bankers, the London and Westminster Bank (Limited), Lothbury, E.C.; or of the solicitors, Messrs. Ashurst, Morris, Crisp, and Co., 6, Old Jewry, E.C. The secretary, *pro tem.*, is Mr. W. G. M. Mackenzie. A strong Board of Directors is associated with the Company, including Viscount Bury (Chairman), Lord Egerton of Tatton, Mr. Thomas Fuller, Mr. Moritz Immisch, Mr. James Paxman, Mr. James Pender, and Mr. Robert Macpherson (Managing Director).

NAMAQUA COPPER COMPANY (LIMITED).—At the ordinary general meeting of this Company, held on Wednesday, Mr. T. K. Weir, in seconding the motion for the adoption of the Directors' Report, alluded to the enormous increase of the consumption of copper in the United States, owing, in a very great measure, he believed, to the immense demand that had taken place for electrical purposes. He understood that for telegraph wires they now used copper instead of iron enormously. Telephones, too, were now to be found all over the country. A man who lived only a few miles from a station or town had his telephone; and he believed that had been, to an enormous extent, the backbone of the increase there. In this country, they might almost say that, as far as electricity was concerned, it had still not emerged from infancy; although there was a good demand for it, it did not compare with what had taken place in the States.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of 76 Six per Cent. Mortgage Debentures, amounting to £7,600, drawn for repayment on and after June 30th, at the National Bank of Scotland (Limited), 37, Nicholas-lane, London, E.C.

STOCK EXCHANGE.—The Committee have ordered the undermentioned to be quoted in the Official List:—United River Plate Telephone Company (Limited), further issue of 3,000 shares, Nos. 55,001 to 58,000.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended May 15th show an increase of £58, as compared with the corresponding period.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 23rd, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,584.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

FACTORY.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 629.—Vol. XXV. FRIDAY, JUNE 6, 1890. Price Fourpence.

NOTES.

The experiments of Mr. Kennelly, which we describe in another column, are deserving of close attention, as they were designed to make clear a part of magnetic theory which has hitherto received but little notice. Weber's theory of magnetism, as found modified in Maxwell's treatise, although, perhaps, the most generally accepted theory, and a most able contribution to magnetic literature, yet forms the least satisfactory chapter in Maxwell's book, and is quite out of keeping with the rest of the work. The assumptions made are arbitrary, and the adjustable constants introduced are so numerous that the mere agreement of the formulæ with the facts proves nothing. Permanent magnetism and hysteresis are partially accounted for, but no indication is given of any possible critical states of magnetism, such as are known to occur with iron; and it is in reference to these latter facts that Mr. Kennelly's suggestions are of value.

Consideration of the influence of molecular stress leads to the conclusion that the permeability at right angles to the lines of force should be greater than that in the direction of magnetisation; and this view was practically tested by measuring the inductance of a coil whose core was placed perpendicular to the lines passing between the poles of a large electro-magnet. The inductance of the coil for very small currents is a measure of the permeability required; and, as it is shown theoretically that with an isotropic medium this is the same as the permeability in the direction of the chief magnetisation, a comparison of the measured inductance of the coil with the permeability of the core, for the magnetism produced by the electro-magnet, indicated whether the iron could be regarded as isotropic or whether molecular actions were modifying the results.

The experiments were only partially successful; but some interesting results were obtained with wrought iron, for which the curves of inductance and permeability showed some marked divergences when the magnetising forces corresponded with certain critical stages in magnetisation, as, for instance, the Villari critical point. Having thus confirmed the idea that molecular stresses considerably modify magnetic phenomena, Mr. Kennelly sketches a theory, which, although it does not, like Maxwell's, lend itself readily to calculation, yet easily accounts for the character of most magnetic phenomena, and even for such a condition of instability as Prof. Ewing has recently called attention to, and of which no explanation has hitherto been offered. The theory is a modification of the ring theory of Prof. Hughes, and, though offering no explanation of the ultimate magnetism of molecules, simplifies matters by concentrating attention on lines of force. The molecular magnets arrange themselves in closed rings just as lines of force do, and an increasing magnetic force first distorts and ultimately disrupts the rings at a certain critical value. By attributing to the medium elastic and other properties, the result of this disruption may be made to resemble what happens in various kinds of magnetic bodies.

The recent annual meeting of the American Institute of Electrical Engineers was marked by a new departure in the shape of a visit to Boston, where the Papers, with one exception, were read. There is, perhaps, no better criterion of the solid progress which any industry has achieved than the number of technical Papers which are read at the various societies connected with it. In the early days of rapid development the numerous problems remaining to be solved give rise to animated discussions. But as soon as things begin to settle down into regular grooves the natural result is that the attention is diverted to some other branch more fruitful in interesting questions. Judging from the increasing number and importance of the electric traction Papers read at meetings such as that just held at Boston, and the comparative paucity of those on electric light, it would seem that this latter branch of the electrical industry in the United States is gradually becoming as crystallised as is, for instance, submarine telegraphy.

From the description we are able to publish this week it will be seen that Dr. Duncan's motor has the distinct advantage, so successfully shown in Mr. Mordey's dynamo, of having the moving parts of iron while the current-bearing coils are stationary. The field-magnets are indeed somewhat similar to those designed by Mr. Mordey for his well-known alternator, the difference being that the polar projections on one side are opposite the spaces between those on the other. The peculiar system of winding adopted will diminish sparking at the brushes, and the great number of poles and armature coils will render possible steady and efficient action at low speeds. These advantages are, however, purchased at the expense of great complexity of manufacture. A commutator of 420 segments divided into 28 groups is somewhat appalling.

Digitized by Google

THE automatic principle, which has developed into something of a nuisance in this country, has been made use of across the Channel in a very characteristic manner. Listening to distant operatic and theatrical performances by means of the telephone has long been the vogue in Paris; and MM. MARINOVITCH and SZARVADY, who have devoted considerable attention to this branch of telephony, have now devised a very complete automatic system. Circuits connect the principal theatres and places of amusement to a central exchange, whence wires are run, or, rather, will be run, to the large hotels and clubs. Here "theatrophones" are installed, and by inserting the requisite coin in the proper receptacle anyone is placed in a position to enjoy as much of a performance as the condition of the apparatus, the state of the weather, and the length of his purse will permit. The approach of an *entr'acte* is automatically announced by the falling of an indicator over the "theatrophone," so that there is no need for money to be wasted. As the fee for a five minutes' "audition" is only 50 centimes, this method of listening to a performance is not very costly, when we consider its novelty and the saving of tissue it affords.

THE steady diminution of the copper stocks, which has now been taking place for some time past, has had its natural consequence in a steady rise of prices. This time last year—that is to say, three months after the collapse of the corner—copper was to be had for about £41 per ton; at the present moment the average price is close upon £55, a rise of over 34 per cent. Electric supply companies, especially those employing low-tension systems of distribution, will be the most affected by this state of things, owing to the impossibility of finding a suitable substitute for copper for their mains. Dynamo builders, the telephone companies, and the Post-Office, will, no doubt, regard this enhanced price with tolerable equanimity, owing to the variety of ways in which they can avoid being unduly hampered by dear copper, the experience they gained in this direction during the existence of the corner being considerable. Prices are still rising, though it is not very probable that copper will attain the prohibitive figure of £100 per ton, at which it stood at the end of 1888.

Stockton.—The Corporation have obtained the Provisional Order applied for by them.

The Cabanyes Battery.—*El Telegrafista Español* announces that the Cabanyes primary battery is to be used for lighting two rooms in the Royal Palace at Madrid.

Trient.—The streets of the old episcopal city of Trient are now lighted by electricity. Trient is the first city in Austria proper to adopt the electric light municipally.

The Yorkshire College, Leeds.—As will be seen by our advertisement columns, the post of demonstrator and assistant lecturer in physics at this college is now vacant.

Tabasco (Mexico).—This town, which has a population of 100,000, is to be lighted by 100 arc lights of 1,000 candle-power, for the sum of 10,000 pesetas (£400) per annum.

Moscow.—According to consular reports, progress at Moscow appears to have begun at the wrong end; both the electric light and the telephone are largely used, but the city is still without drainage or waterworks.

Magdeburg.—The want of an electrical testing station in North Germany has long been felt, and it has been decided to open one at Magdeburg, under the directorship of Dr. Martin Krieg, chief editor of the *Elektrotechnisches Echo*.

Bridlington.—At a special meeting of the Local Board last week, it was resolved, *nem. con.*, to accept the offer of Messrs. Laing, Wharton, and Down, to light the Princess-parade during the season with 7 arcs and 33 incandescents for £50.

Italian Duty on Accumulator Plates.—According to *l'Elettricità*, the Italian Custom House officials have decided that accumulator plates are to rank as parts of a dynamo, and must therefore pay a duty of 6 francs per quintal (1 cwt. approx.).

The Laurent-Cely Accumulator.—With reference to this accumulator, a brief description of which appeared in our last issue, we are informed that the English patent for the same was refused in January, 1889, by the Comptroller-General of the Patent Office.

Canterbury.—At an adjourned meeting of the Town Council on Wednesday last week, the electric light question was again considered; and it was unanimously decided on the recommendation of the Committee, that the Council should apply for a Provisional Order.

Wimbledon.—A public meeting of ratepayers has been called for the 12th inst. to hear their view of the electric lighting question. The Local Board, it will be remembered, decided last March to adopt the electric light in place of the present system of oil lighting.

Fire Alarm Experiments.—Some experiments took place at the Bradford Fire Brigade Station last week before several members of the Watch Committee, a number of manufacturers, insurance agents, and others, with an electrical alarm of the Automatic Heat Regulator and Fire Alarm Company, of Birmingham.

Electricity and Spiritualism.—At the forthcoming assembly of the London Spiritualistic Alliance, to be held on June 12th, at the Banqueting Hall, St. James's Hall, at 7:30 p.m., Mr. Desmond Fitzgerald, M.I.E.E., will deliver an address entitled "My Experiences in Spiritualism: a Word with Sceptics and Spiritualists."

The Telegraph in Burmah.—The telegraph line now being constructed from Chittagong to Burmah is, says *Indian Engineering*, making good progress. It is already laid on the east side to Haka, and on the west side to Fort Tregear. When the intervening space of some sixty miles only is completed there will be uninterrupted intercourse between Chittagong and Mandalay.

Earthquakes and Atmospheric Electricity.—At a recent meeting of the Japan Seismological Society in Tokio, Professor Milne showed from automatic records of atmospheric electricity that whenever there has been a severe shock of earthquake of which Tokio was at or near the *epicentrum*, the air suddenly has become negatively electrified, and has required several hours to return to its normal condition.

Kieff.—The British Vice-Consul has recently reported to the Foreign Office that there seems every prospect of the electric light being introduced at Kieff. The place, according to his report, is an ideal town for an electric light installation, the principal streets and public buildings being all within an area having a radius of less than a mile. The matter is, the Vice-Consul states, well worthy the attention of English companies.

Electricity and Microbes.—In a recent communication to the Académie des Sciences, MM. Apostolli and Laquerrière state that the general conclusion which they draw from recent researches is, that continuous currents of electricity, of the strength usually employed in electro-medical work, have no effect *sui generis* on microbes placed in a homogeneous medium, but that the destructive effects observed are due to the disengagement of acids and of oxygen.

The Boston Elevated Railway.—The Bill of the West End Street Railway Company to construct an elevated railway through the streets of Boston, U.S., is meeting with considerable opposition. The Bill contains a provision which permits the

Digitized by Google

use of electricity as the motive power for the cars, and the West End Company contemplates the transfer of the street electric cars to the elevated track by means of an inclined plane.

The Copper Market.—The stock of copper in France, in England, and afloat has, according to Messrs. H. R. Merton and Co.'s statistics, fallen to 82,041 tons, compared with 90,230 tons at the end of April last, and 117,420 tons a year ago. The deliveries in France and England were extraordinarily large last month, being put at 17,030 tons, or fully three times the monthly average in the year of the Copper Syndicate (1888).

Personal.—Mr. Frank B. Lea, who has been the editor of our contemporary, *Electrical Plant*, almost since its initiation three years ago, has, we hear, severed his connection with that journal. Mr. Lea proposes to devote his attention to work of a more practical kind in the field of electric transmission of power; and we trust that his efforts in this direction will meet with the same success that characterised his journalistic labours.

Sheffield.—At a meeting last week of the Parliamentary Powers Committee of the Town Council the following resolution was moved and carried:—"That, considering the present position of the question of supplying electricity in large towns, and the probability of applications for power to do so in Sheffield being made by outside companies or persons, the Committee recommend the Council to adopt the needful steps for obtaining power themselves to supply electricity within the borough."

Paddington Vestry.—A Special Committee has been appointed to secure the insertion, in the Order of the Metropolitan Electric Supply Company now before the Board of Trade, of the various amendments agreed between the Vestry and the Company. A memorial signed by several members of the Vestry has also been sent to the President of the Board, calling attention to the "irregular procedure" of the Vestry, and requesting the Board of Trade, under the circumstances, not to grant the Order.

Edinburgh Exhibition.—A meeting of the London Committee of the Edinburgh Exhibition was held at the Mansion-house on Tuesday. Mr. Lee Bapty gave some particulars with regard to the progress of the Exhibition. The visitors in the first month had numbered 470,000, which was largely in excess of the most sanguine anticipations. If the same number of visitors continued each month until October, there would be a total of over four millions. The French electrical exhibits had, he stated, just arrived.

Dinner to Sir James Anderson.—On Wednesday evening a complimentary dinner was given to Sir James Anderson, at the Café Durand, Paris, to celebrate his birthday and the fiftieth anniversary of the date of his going to sea. Mr. Thomas Fuller presided, in the absence of Sir John Pender, and the representatives of most of the telegraph companies attended. An illuminated address was presented by Mr. Charles Burt, on behalf of the gentlemen who had signed it, in which reference was made to the services rendered by Sir James in connection with the laying and repair of submarine cables.

Lightning.—On April 8th, Louvain Cathedral was struck by lightning. One of the turrets was completely destroyed. The top, weighing about 4 tons, was projected a distance of 22 yards, demolishing a house, while blocks of stone weighing from 2 to 3 tons were hurled a distance of nearly 70 yards, damaging the houses in the neighbourhood.——During a recent sitting of the Berlin Town Council, says the *Elektrotechnischer Anzeiger*, the municipal buildings were struck by lightning. The discharge followed the electric light leads, shaking the lustre of the room in which the sitting was being held, and causing the incandescent lights to flare and blacken the glasses. No damage was done.

Institution of Civil Engineers.—The following particulars are taken from the report read at the annual general meeting of this Institution on Tuesday last. At the close of the past financial year the number of members was 5,872, and the gross receipts for the twelve months amounted to £22,478. Amongst the honorary members elected during the past year was Sir William Thomson. The Manby Premium was awarded to Messrs. W. P. James Fawcus and E. W. Cowan, who recently read a Paper on "The Keswick Water-power Electric Light Station," and a Miller Scholarship was awarded to Mr. C. Frewen Jenkin for an electrical Paper read at a supplemental students' meeting.

Helston.—An Art, Industrial, and Electrical Exhibition was recently held at Helston. The electrical exhibits comprised electrical apparatus and appliances shown by Mr. W. Slade Olver, jun., of Falmouth, and a large collection of telephonic apparatus lent by the Western Counties and South Wales Telephone Company. There were also lectures on the construction and use of telephones, by Mr. Olver, and telephonic concerts, transmitted over a mile of wire. Each evening the hall was lighted by electricity by Mr. Olver, the installation consisting of two 2,000 candle-power Gulcher arc lamps, two 500 candle-power Sunbeam lamps, and a large number of smaller incandescent lamps, driven by a large dynamo of the Gulcher type.

Fulham Vestry.—A special meeting of this Vestry was held last week for the purpose of considering the question of taking action to facilitate the introduction of the electric light into Fulham. The motion embodying this determination was carried by 32 to 20. Subsequently it was proposed that the House-to-House Electric Company should receive the consent of the Vestry to apply to the Board of Trade for a Provisional Order to supply not more than one-half of the parish with electric light, such area to be fixed by mutual arrangement, the Vestry's right to lay mains and supply electric light to any part of the parish at any time not to be prejudiced by such consent. The motion was lost, and the matter was ultimately referred to the Lighting Committee.

Presentation to Mr. Bernard Drake.—The staff and *employés* of Messrs. Drake and Gorham, who now number upwards of 80, presented Mr. Bernard Drake with a handsome plate chest, containing an assortment of silver plate, on the occasion of his marriage on May 28th. Mr. Drake, in thanking those who had subscribed towards this gift, said they all knew what importance he attached to an absolute unity of interests between employer and employed, and he should like to take that opportunity of thanking them all for the very loyal way in which they had always worked for the welfare of the firm. He liked them all to feel that as the business increased and prospered their individual interests were watched. Their object was, and always would be the same, viz., to do better work than anyone else, to employ better men, and pay better wages.

Obituary.—At the last meeting of the Académie des Sciences, M. A. Cornu gave a brief sketch of the life's work of M. Jacques-Louis Soret, who died on the 13th May. M. Soret was born at Geneva in June, 1827, and came to France at an early age, where he worked as one of Regnault's assistants. M. Soret at first devoted his attention to electrical research, and his study of the laws of electrolysis led him to define the conditions favourable for the production of ozone and to determine its density and chemical constitution. His investigations on the subject of the co-relation of physical forces contributed to the elucidation of the then obscure connection between electric currents, heat and mechanical energy. M. Soret also did classic work in other fields, such as optics, solar radiation and the seismic movements of the earth.

The Cuttriss Calculating Disc.—This calculating disc is an improved form of slide rule, by means of which a great variety of mathematical calculations can be performed. The instrument consists of a thin metal disc, round the circumference of which slides a ring of corresponding thickness, both the disc and the ring having scales engraved upon them. Two scales are engraved on the disc, and two on the ring, and by placing the scales in definite relative positions with each other, calculations can be readily performed, involving multiplication, division, proportion, vulgar and decimal fractions, powers, roots, and a large variety of problems. With a little practice and by the aid of simple constants many problems specially useful to electrical engineers may be rapidly worked out. The very portable and simple nature of this calculating disc seems to render it eminently suitable for use in outdoor work.

Electric Lighting Provisional Orders.—The Board of Trade has granted Provisional Orders relating to Cambridge, Dover, Hove, Walsall, Wolverhampton, Worcester, Burnley, Bury, Chester, Fleetwood, Lancaster, Salford, Bacup, Bedford, Crompton, Huddersfield, Malvern, Oldham, Stockton-on Tees, Accrington, Barnsley, Blackpool, Burton-on-Trent, Cheltenham, Darlington, Bournemouth, Derby, Hastings and St. Leonards, Oxford, Portsmouth, Woking, Birkenhead, Great Yarmouth, Kingston-upon-Hull, Nottingham, Wigan, York, Belfast, Blackburn, Leicester, Morecambe, Sevenoaks, Tunstall, Ayr, Bognor, Eastbourne, Galway, Stafford, and Tiverton. Provisional Orders have also been granted for the following Metropolitan districts:—Lambeth, North London, St. James's, Westminster, St. George-the-Martyr, Southwark, and a portion of the parish of Camberwell, and Wandsworth. The Bills confirming these Orders now stand for second reading.

St. Pancras Vestry.—At a meeting of this Vestry last week Mr. Sweet moved that, in lieu of re-electing a joint committee of the Parliamentary and the Lighting Committees to carry out the work of electric lighting, a special committee be now appointed to carry out such work. That the special committee consist of eighteen members, to include representatives from each ward. That it be an instruction to the committee to report their transactions at the first meeting of the Vestry in each month. It was eventually decided to elect two members from each ward, with one extra from Wards 1 and 3, and the two churchwardens.—At the last meeting of the London County Council, the Finance Committee reported in favour of the application of the Vestry of St. Pancras for the advance of £10,000 to purchase a site for an electrical installation for the south-west portion of the parish. They recommended that the loan be granted on condition that it be taken up at once, interest being charged at the rate of 3½ per cent. and the principal being repaid by equal annual instalments within a period of 50 years. This was agreed to.

Annual Conference of the Postal Telegraph Clerks' Association.—On Saturday last the annual conference of this Association was held at Leicester, when about 60 delegates attended. In consequence of the Postmaster-General's insisting upon the presence of an official reporter, the names of the various speakers were suppressed. A resolution was adopted to the effect that, inasmuch as the Postmaster-General now states that he brought no charge against the Cardiff clerks, a request be sent to Mr. Raikes for their reinstatement. A proposal to affiliate the association with the Trades Council of the United Kingdom was referred to the district centres for consideration, and the Trades Councils were thanked for the services which they had rendered to the Association. A resolution was adopted thanking the Postmaster-General for having referred some of their demands to a departmental committee, but declining to accept the decisions of that committee as final. A long discussion took place on the action of the Postmaster-General in insisting on the presence of an official reporter at their meetings outside the Post Office buildings, and the course adopted by Mr. Raikes was strongly condemned.

The International Telegraph Conference.—A banquet was given on Friday last by the British Chamber of Commerce to the British and Colonial delegates to the International Telegraph Conference. Amongst those present were Messrs. Lamb, Fischer, and Benton, the British delegates; Messrs. Mallock and Brasher, the Indian delegates; Sir Graham Berry, Sir Arthur Blyth, Mr. Aylmer, and Sir Joseph Crowe, commercial attaché to the British Embassy here. On Monday afternoon the delegates to the Conference were entertained at luncheon at the Embassy by Lord Lytton. According to Reuter's telegram, Sir Francis Dillon Bell, Agent-General for New Zealand, is engaged in discussing with the French Government the advisability of reducing to a certain extent the cable rates between France and Australia. Similar proposals will be made by Sir Francis to the German delegates. Should France and Germany consider commercial intercourse with Australia important enough to enter upon a discussion of the matter now, rather than postpone it until the next Conference, five years hence, and should they be induced to share with Australia the risks involved by the reductions, Sir Francis Bell will submit the question for discussion to the Telegraph Conference. The Agents-General of the Australian Colonies have made application to the Secretary to the Colonies and the Chancellor of the Exchequer, asking for an appointment to discuss the reduced cable tariff scheme.

The "Peral" Electric Submarine Boat.—The "Peral" submarine torpedo boat, which is of the usual cigar shape, is provided with four screws, two vertical ones for effecting immersion, and two for purposes of propulsion. The screws are driven by Immisch motors run off specially constructed Julien accumulators, having a high output for weight. Matters have been so arranged that if any accident occurs to the motors and the immersion screws are stopped, the boat rises at once to the surface without further aid, though, of course, the emptying of the water compartments hastens the ascension. To avoid an undue expenditure of power in connection with the immersion screws, the water compartments are filled to an amount which enables a very slight motion of the screws to sink the boat to the required depth, and maintain it there. The automatic apparatus which regulates the depth at which the boat is to work is designed on a principle somewhat similar to that of the aneroid barometer. A curved tube of elliptical section is placed in connection with the sea, and its deformations due to the alterations of pressure actuate a switch, by which the strength of the current going to the immersion screws is varied. The positions of the contacts of the switch are altered to suit the particular depth at which it is required to work. A very sensitive automatic electrical device is also employed to keep the vessel in a horizontal position. The apparatus consists of a pendulum playing between two contacts. If the boat is not perfectly level from stem to stern, the pendulum touches one of the two contacts, and the result is that the corresponding vertical screw is actuated and the boat is righted. The speed which the inventor hoped to realise, namely, ten miles an hour, has been much exceeded.

Electrical Engineering at Columbia College.—In the April number of the *School of Mines Quarterly*, Mr. F. B. Crocker gives a brief description of the Electrical Department at Columbia College, and the following extracts may be of some interest. The facilities for obtaining electric current of different kinds and in large quantities are, he says, particularly satisfactory. Continuous current to the amount of 100 amperes under pressure of either 110 or 220 volts may be had at numerous points in all the rooms from a specially installed circuit of the three-wire system connected with the Edison 39th street station. Available at adjacent points and parallel to this circuit is another special circuit of equal capacity on the two-wire system coming from the Edison dynamos of 400 lights total capacity in the cellar. A third special circuit, also of 100 amperes capacity, has been put in to connect dynamos, motors, &c., in the electrical workshop down stairs with measuring instruments in the upper laboratory, which is devoted to delicate work. A storage battery circuit available at convenient points in the various rooms is to supply current under an E.M.F. of a few volts for testing purposes, galvanometer work, electrolysis and the many other duties which are generally performed in the laboratory by a number of separate primary batteries with their attendant inconveniences. The buildings are lighted entirely by electricity from the regular circuits. Gas for heating and other purposes may be had wherever needed from pipes fitted around the walls of each room just below the ceiling. The connection with the Manhattan Company's alternating circuit has lately been cut off by the city authorities, but alternating current and arc light dynamos are soon to be put in in order to avoid this unpleasant contingency. The students have just finished the construction, for experimental purposes in the laboratory, of a battery of 1,280 cells, which, when set up with Daniell elements, gives an E.M.F. of about 1,400 volts, and when set up as a storage battery, an E.M.F. of about 2,800 volts. Some interesting results have been obtained from the experiments performed with this battery. There has just been erected in the Mechanical Engineering Department a hydraulic testing-machine of 150,000 pounds capacity, and it is now to be used by the electrical engineering students for a series of tests which, it is expected, may be of considerable theoretical and practical interest in electrical science.

ON THE PERMEABILITY OF IRON AT RIGHT ANGLES TO THE DIRECTION OF MAGNETISATION.

BY A. E. KENNELLY.

Weber's theory of magnetisation, in the modified form suggested by Clerk-Maxwell, is that which appears to meet with the most general acceptance; and it is a notable feature of this theory that it considers the restituting forces acting on the molecule to be a function only of their displacement angle, and to be independent of any mutual reactions between the molecules themselves during magnetisation, or of the influence which combination in polarity might exert upon the equilibrium of their intermolecular forces.

The intimate relations which have been found by so many observers to exist between the mechanical and magnetic conditions of iron in the mass, such for instance as its alteration in dimensions by magnetisation, the change of its magnetic properties under mechanical stress, the sounds emitted by iron bars under electromagnetic impulses, and the variations in the permeability of iron under varying temperatures, all suggest the *à priori* probability that the orientation of the molecules supposed to take place during magnetisation would call into play molecular reactionary forces of a mechanical or magnetic nature, whose effect upon the process would not be negligible, especially in advanced stages. It might be expected, in fact, that these molecular reactions would impede the progress of magnetisation to an extent increasing as that process was continued towards the maximum limit. Among the wide variations in magnetic behaviour exhibited by different specimens of iron differing sensibly in constitution, and the consequent latitude that a theory including all of them must possess, it would be difficult to detect the influence of any such reactions by direct calculation or comparison; but their effect would probably be to increase the apparent relative permeability of iron at right angles to the direction of magnetisation. That is to say, feeble magnetic forces brought to bear upon strongly magnetised iron would probably produce a greater magnetic displacement at right angles to the existing magnetisation than when co-incident with it in direction, owing to the expected absence of reactionary forces in the former line.

The experiments about to be described were made with the object of detecting any such difference of permeability if it existed. The results may be considered to have rendered a difference distinctly visible in the case of one sample of wrought iron, but with the specimens of cast iron and steel also tested, the conclusions are doubtful; for although the values obtained for their permeability are certainly greater than theory would warrant, they are not much more divergent than those obtained by the same method for their permeability in the direction of magnetisation itself.

While the success of the investigation has thus been only partial, the interest which attaches to the subject will perhaps be sufficient excuse for their complete presentation in condensed and tabular form.

The first experiments were made with a hollow cube of cast iron, 6 centimetres in length of edge. Two opposite sides of this box were wound with narrow coils of insulated copper wire passed in and out through slits suitably cut. By placing the box between the poles of a powerful electromagnet, the magnetic flux could be made to pass through one pair of coils and parallel to another pair. The electro-magnet was gradually excited, and the induction through the sides of the box measured by ballistic galvanometer, while the inductance of the coils across the flux was compared with that of the coils wound parallel to the flux by means of the secohmeter.

The measurements, several times repeated, all agreed in showing that the coils across the flux were most reduced in inductance as the flux itself increased—that is to say, the apparent permeability of the iron across the flux was the greater, the ratio being, in fact, about 2·5 to 1 at an induction of 11,000 C.-G.-S. line per square centimetre through the sides of the cube.

On closer examination, however, a serious source of error became evident that ought to have been foreseen at the first. The lines of force issuing from the coil parallel to the flux could not be confined to paths intersecting the flux at right angles; and the many stray lines round the ends of the coils, along the main path of induction, produced an error in the measurements too great to be neglected and too complex to calculate. The cube was therefore abandoned in favour of a more unexceptionable arrangement.

Four rings were then prepared, of practically equal dimensions and rectangular cross-section (Fig. 1), one of wood, the second of ordinary wrought iron, and the other two of cast iron and tool steel respectively. The particulars of their dimensions are given in Table I.

These rings were each wound with copper wire 0·036 centimetre diameter silk, covered to 0·046 centimetre in one complete layer of 289 turns, over oil-paper. The weight of this layer was 18·5 grammes, and its resistance 2·2 ohms at 22° C.

The inductance of these solenoids was then measured, with the results, in Table II., using a bridge, standard subdivided condenser, and secohmeter for reversals, by a modification of Clerk-Maxwell's method.

The somewhat low degree of precision in these measurements indicated by the probable error is due to the difficulty so often met with in measuring the inductance of coils surrounding soft iron, with feeble testing currents. The strength of the testing current in the above series was 29 milliamperes at the maximum steady value, from which H would be 0·53 in each coil.

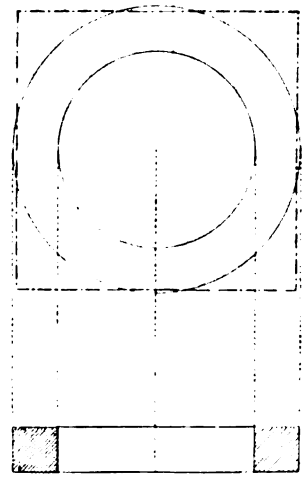

FIG. 1.—Iron Rings. Plan, and Diametral Section. Scale ½. Rectangle drawn — · — · — represents polar face.

The rings were then placed in succession symmetrically between the poles of the above-mentioned electro-magnet, so that the magnetic axis apparently coincided with the axis of the ring. The polar faces were planes 7·3 centimetres by 7·4 centimetres, and were kept apart 1·6 centimetres by corner wedges so as not to compress the ring. With the magnet unexcited, the inductance of the rings was found to be not sensibly altered by the presence of the iron poles; but on powerfully exciting the magnet, that of the three iron rings fell to quite a small percentage of its normal value, viz., wrought iron to 20 per cent., cast iron to 13·8 per cent., and tool steel to 25·4 per cent., the original values being restored on the cessation of the exciting current in the coils of the electro-magnet.

Steps were next taken to measure and control the amount of this magnetic flux across the ring, observing the inductance at each step. For this purpose five turns of fine insulated copper wire were wound on the external periphery of each ring, and five similar turns applied to the inner periphery by winding them on a closely fitted cork. The induction through these two windings at each stage of the magnetisation was measured in the usual way by electro-magnet reversal and ballistic galvanometer.

The difference between these inductions, slightly corrected for winding space occupied by the solenoidal coil, being the total flux through the ring normal to its plane, the mean value of the induction per square centimetre was immediately determined. The induction in the solenoid was similarly observed to make sure that no great error was involved by any want of accuracy in the alignment of the ring axis between the

poles, this induction being, of course, with perfect alignment equal to that through one turn round the external periphery.

The results obtained in this way with each iron ring are given in Tables III, IV., V.

The exterior and interior turns were next removed, and a primary solenoidal winding of cotton-covered wire laid on each ring over the original layer now used as a secondary. This done, the rings were magnetised in the usual circular manner by measured currents through the primary coil, while the corresponding induction through and inductance of the secondary layer were observed at each step. This determined the inductance of the coil corresponding to each value of the magnetising force and circular induction per square centimetre. The results with each ring are given in Table VI.

(To be continued.)

THE WIRING OF HOUSES FOR THE ELECTRIC LIGHT.

BY E. C. DE SEGUNDO, ASSOC.M.INST.C.E.

To those whose lot has been cast among "pioneering" electric light ventures, and who have been connected with electric light companies from the time of their formation, it will be apparent that perhaps the one thing which has militated against the extension of electric lighting amongst private consumers more than another has been the large first cost of installing a house with the necessary wires. Another cause is the endless dissension which has arisen from time to time between supply companies and contractors as to the lines on which a house should be wired, unnecessarily complex safety precautions being frequently insisted upon. It is a good fault, no doubt, "to err rather on the right side;" but, in the face of the experience which has been gained in the fixing and maintenance of electric light wires, there should be no longer any necessity to err at all, whether on the right or on the wrong side.

To encourage competition is very right and proper; but it is possible to carry this principle too far in order to get rid of personal responsibility. If A manufactures a better article than B at the same price there should be no hesitation among those whose duty it is to discriminate, to pronounce in favour of A unequivocally. If A's article at price x is better than B's article at $(x-a)$, (where a is a positive quantity), it is quite possible that the ratio $\frac{\text{quality of A's article}}{x}$ may be numerically equal to $\frac{\text{quality of B's article}}{x-a}$, and, within certain limitations, there might be no reason why A should be recommended rather than B. If, however, the use of B's article involves so great an element of risk or danger as to render its introduction unadvisable, there can, of course, be only one opinion of the authority who favours B. A great many of the incidents which have tended to hamper the progress of, and throw discredit on, electrotechnics here as well as in the States, have been due to B's article having been specified—for a consideration—where A's should have been used; and there cannot be the shadow of a doubt that if electric lighting is to make rapid and honourable progress, consulting engineers and supply companies should lose no time in deciding whether they will tolerate the use of B's article when A's should be used; and should make a firm stand, insisting upon work being done as they know it should be done, and not allowing themselves to be swayed in any direction by the expressions of opinion of interested parties.

It is impossible to read any of the rules drawn up by insurance companies without feeling that the compiler is unwilling to commit himself to any unequivocal expression of opinion; the saving clause, "in special cases the work is to be done to the satisfaction of the inspector," is frequently met with at the close of a paragraph. One is naturally led to ask, what constitutes a special case? For surely that is very much a matter of opinion; it would seem more reasonable to specify that in cases of differences of opinion, as to what is safe and what is not safe, the matter should be referred to competent arbitration.

As an instance of the unsatisfactory nature of some of the specifications in the schedules issued by supply companies, take the allowable intensity of current according to some of the supply companies' specifications. It is 1,000 amperes to the square inch. This stipulation seems to be of a somewhat apologetic nature. It allows the greatest possible benefit to the installer and the least possible—consistent with the fear of complaints as to the intensity of the light in various parts of the house—to the consumer. The installer as a rule is not so overburdened with cash as to be able to afford to quixotically put more copper in the mains than he is obliged to; the consumer, on the other hand, is usually a man by whom a few pounds more for copper would not be grudged, if the advantages were made plain to him; the supply companies, if their interests alone were considered, would specify 100 amperes to the square inch in the houses, or other parts of the distributing system they don't pay for, in order to save coal.

The 1,000 amperes specification seems to be an attempt to please all parties concerned, as far as possible; but it is obvious that in a large house anything like 1,000 amperes per square inch at full load would cause an appreciable drop in the furthest lamps. Of course, no good firm of installers wires at an intensity of over 600 amperes per square inch at full load for any distance; but at present the demand is so large compared to the supply that the numerous contracts run away with by small and untrustworthy firms are not noticed in the crowd. These small and inefficiently performed contracts, however, do not tend to add to the reputation of electric lighting in the estimation of the general public. The consumer who had paid for the wiring of his house under the conditions of "best workmanship" and "best materials," naturally turns to the supply company to remedy the 5 per cent. drop in his bedroom lamps. The company send up their representative to test, and discover the true state of affairs. This cannot be appreciated by the consumer, who is, naturally, in nine cases out of ten, not a technical man; and then begins the wrangle between contractors, consumer, and supply company. The contractors maintain that 1,000 amperes is allowed by the supply company; and so the unfortunate consumer finds himself in a difficult position, inasmuch as he is mixed up in a dispute on a matter that he does not in the least understand. It does not mend matters in the slightest to urge upon the consumer that electric lighting, *per se*, is not to blame, and to attempt to demonstrate the philosophic axiom that all things are good, the abuse of them only constituting evil; he does not wish to see the matter in that light, and does not hesitate to express his views to his friends as to his practical experience of electric lighting.

Obviously, not only is it advisable in the interests of electric lighting, but it is necessary in the interests of the consumer and the company, that the 1,000 amperes per square inch specification should be qualified by a maximum permissible difference of percentage of drop in the potential at the terminals of the furthest lamp, at light-load and full-load. If these conditions were fulfilled the company would feel sure that consumers would be receiving from their lamp the proper intensity of light as long as the potential in the supply mains was up to standard. They would further be able to judge with more accuracy the efficiency of their system, as they would then know the maximum loss to be allowed for each house supplied. The only party likely to object to this is the cheap contractor, the man who will undertake to put in the best work, the best materials, the latest improvements, &c., for 18s. a light.

The question of allowable current intensity is, of course, only one of a large number which have to be considered, and there can be little doubt that there is plenty of need for consideration and reconsideration in these matters. Supply companies would do well to realise more fully, or perhaps we should say, act as if they realised the great importance to them of sparing no pains to counteract the growing idea that having the electric light in one's house necessarily entails a great deal of worry, and annoyance, and possibly litigation. Early supply companies have done much to hamper the extension of electric lighting by their disregard of the annoyance to which their con-

Digitized by Google

sumers were subjected owing to "steam getting low," machine No. so-and-so breaking down, and kindred occurrences which should never, and would never have happened if so important a matter as the control of the plant for the supply of light to private consumers had been placed in the hands of reliable men, and not relegated to mere boys whose ideas of duty were somewhat limited, and who seemed to in no way appreciate the grave responsibilities they incurred in virtue of their position. There can be little doubt that what applies in commerce applies also in electric lighting, namely, that the firm which treats its customers best will in the end be the most successful, and thus there can be little fear of contradiction if it is asserted that the greatest discretion should be exercised in the choice of a superintendent for an electric lighting centre, and that the supply companies' specification for the wiring of houses to receive current should be revised with a view to the protection of themselves and their non-technical clients.

The following suggestions are put forward in no dogmatic spirit, but merely as an attempt to point out in what direction reform might usefully take place. It is not intended to lay down such complete and detailed instructions as shall apply to every possible case.

Questions connected with unusual circumstances which call for unusual precautions must, of course, be left to the authority who is responsible for the general character of the work; and, indeed, it would be idle to attempt to frame so complete a code of laws as would in themselves constitute an all-sufficient source of reference; but there can be no doubt that in one or two important details the requirements in the specifications of supply companies and insurance offices could well afford to be made more definite. One has already been mentioned, namely, the question of intensity of current allowable in the conductors. This is contained in Section 2 of the "Phœnix Rules." It is stated, first, that "all conductors are to have sufficient sectional area to allow at least 100 per cent. more electricity being safely sent through them than will ever possibly be required for the lights they supply." Then comes a sub-section, "Under normal conditions for internal work the ratio, 1,000 amperes per sectional square inch of copper, is a fair proportionate quantity of current to send through a conductor when the amount passing through the said conductor does not exceed 100 amperes." The portion quoted leaves one in doubt as to whether—(*a*) 1,000 amperes per square inch, &c., is the allowable intensity when the 100 per cent. extra permissible current is considered to be flowing; if not, (*b*) does "normal" refer to the conditions in every-day work? if so, (*c*) what conditions are to be considered normal? for the load varies with the weather and the time of day or night.

The specified allowable current density per square inch of cross section of conductor should, as before remarked, have regard to the loss due to the resistance of the conductor. It is naturally also necessary to specify a maximum current density, as in the case of short lengths the allowable percentage of loss would not be a sufficient protection. The section governing the intensity of current conductors might be worded somewhat as follows:—

(i.) The current density is in no case to exceed 1,000 amperes per square inch of cross sectional area of a solid conductor of copper containing the same volume of metal per unit of length as the conductor in question. The copper used to be of at least 96 per cent. conductivity. The system of conductors to be so designed that the drop in potential at the terminals of any lamp when at maximum load shall not exceed 2 per cent. of the potential at the point where the current enters the house from the source of supply, whether this be the supply mains of a company or any other source of electrical pressure.

(ii.) The maximum load to be stated by the consumer in terms of the number of watts which he will require.

Another point in regard to which some discussion might be fruitful of good result is the question of fuses. In regard to this matter there is, perhaps, no question in house-wiring on which the adage, "Prevention is better than cure," bears more closely. The practice of using inferior material and then sowing fuses broadcast cannot be too strongly condemned. It is evident that inasmuch as the function of a fuse is to cut off the current supply when the current density becomes so great as to be liable to cause undue heating at any point, it is necessary that in the case of a branch system from any main or sub-main the smallest wire should be efficiently protected.

Thus, if the size of the smallest wire be first determined, the position of the first necessary fuse will be found by working back towards the main. It will be at that point where the current intensity required for the various lamps "picked up" on the way becomes from 75 to 80 per cent. of that which the smallest wire can bear without injury. Now, it is clear that under these restrictions a system of conductors might obtain in which the smallest conductor was of such a size that in the event of a partial short-circuit the fuse would allow enough current to pass to maintain a small arc sufficient to set any inflammable matter near the short circuit on fire. Clearly, then, provision must be made for the circuits to be so divided that none will carry a current whose value would ever exceed a safe one before the fuse blew. In the case, for instance, of the gradual breakdown of insulation at any point and the gradual increasing short circuit or earth, the fuse should blow and cut off the current before the leak becomes dangerous. Then, of course, the question arises, what constitutes a dangerous leak? That is a matter which will probably always remain a matter of opinion. Theoretically it would be wise to divide the house to be lighted into sections and lead conductors for each section to a distributing fuse board whence separate leads would be taken off through a suitable fuse for every lamp or group of lamps controlled by a single switch. This, it is asserted, would involve a heavy expenditure; but perhaps when the decrease in cost, owing to the time saved in making joints and the saving due to the fact that conductors of less insulation resistance can be employed, is set off against the increase of cost due to the greater length of conductor used, the difference will not really be so great.

A short circuit can easily be prevented from becoming dangerous by the interposition of suitable fuses. An "earth" is much more difficult to deal with, inasmuch as its "degree" varies with the weather, the state of the building, its capacity for absorbing moisture, and all circumstances which affect the insulation of the leads. Moreover, the real potential difference between either lead or any particular point in either lead and the earth must be more or less a matter of conjecture; hence the intensity of the leak becomes also indeterminate. Obviously it would be unwise to attempt to control the amount of leak to earth by means of fuses used in the ordinary manner; and it appears probable that the only satisfactory way to guard against possible dangers from any earth on the circuit becoming dangerous is frequent testing.

The question of fuses might be dealt with in somewhat the following manner:—"A double-pole fuse to be inserted between a main and a branch wherever the change of section is such that the smaller conductor is not capable of carrying, without risk of injury, the maximum current which the fuse controlling the main will allow to flow, the size of the smaller conductor being conditioned by the number of lamps it has to feed and the allowable percentage of fall of potential difference. Tests of insulation resistance to be made at regular and frequent intervals by a competent electrician, any gradual lowering of the insulation resistance beyond that which might be expected, owing to extraneous conditions (weather, temperature, &c.), to be reported and investigated without delay."

Generally, it might be said that the safest and best principle to go on is to put in work of such quality and workmanship that it may be relied on to protect itself, so to speak, and thus obviate the necessity of placing so much dependence on fuses, particularly as, in the hands of technically uneducated people, fuses become a fruitful source of danger, and as the breaks in the continuity of the casing due to the interposition of many fuses tends to lower the insulation resistance of a circuit. It might, perhaps, not be out of place, in conclusion, to emphasise the advisability of surface work as far as practicable, and to recommend that if surface work is objected to on the ground of unsightliness, it would be wiser to move in the direction of cheapening ornamental casing rather than to hide it between floors and in plaster. There is no reason, for instance, why the moulding at the top of a high dado should not be constructed to receive leads.

THE TREATMENT, REGULATION, AND CONTROL OF ELECTRIC SUPPLY BY THE LEGISLATURE AND THE BOARD OF TRADE.*

BY MAJOR P. CARDEW, R.E.

Mr. President and Gentlemen: Before starting with the undertaking which in a moment of weakness I have laid upon myself, I have to ask a favour and convey a warning. The favour is, that you will bear in mind that nothing I may say to-night possesses any official sanction, or can be taken as in any way expressing the views of the Board of Trade. Before preparing the Paper I obtained permission from the Department under which I serve to do so; but some rather delicate ground is traversed in the Paper, and I am sure I may rely upon your forbearance to-night in any discussion which may arise to avoid any questions of policy. The warning is, that I am painfully conscious that the Paper is very dry and portentously long.

The subject which I have the honour to submit to your notice to-night is "The Treatment, Regulation, and Control of Electric Supply by the Legislature and the Board of Trade." I am afraid the scientific interest of the Paper is very small; but as many of you are practically concerned in the matters dealt with, I hope it will not be considered to be out of place.

The first attempt to deal with the question of electric supply on the part of the Legislature was the Act of 1882. As notice had been given of many private Bills to be brought in to acquire the necessary powers for a general supply, proceeding on very varying lines, it was thought that the time had come for a general Act dealing with the subject. The two principal objects of this Act were—(1) To empower electric supply companies, or persons, or Local Authorities desirous of undertaking this supply for their own districts, to lay their mains in the public streets, and conduct the business of supply generally in a manner recognised by law; (2) to recover charges for supply made to consumers. At the same time proper regulations and conditions were imposed upon the undertakers to secure the safety of the public and the adequacy of the supply; while the fear of creating a new perpetual monopoly was evidently present in the minds of the framers of the Act.

This Act is so familiar that a short sketch of its provisions will be sufficient. It sets out by detailing the various ways in which statutory powers can be obtained. These are—(1) By licence, (2) by Provisional Order, (3) by special Act.

The issue of licences is left entirely in the hands of the Board of Trade, but the consent of every Local Authority affected must first be obtained. The original period for which a licence is granted must not exceed seven years, but it may be renewed with the like consents. A licence may be for "public purposes" or "private purposes." "Public purposes" only allows supply for electric lighting of streets, public places, buildings, theatres, &c.; while "private purposes" allows general supply, not only for lighting, but for any other purpose, except the transmission of any telegram. The Board of Trade is empowered to make such regulations and conditions in a licence as it may think expedient.

Provisional Orders in this Act may be granted without requiring the previous consent of the Local Authorities affected, but have no force unless and until confirmed by Act of Parliament. The period of an Order may be limited or it may be unlimited in duration. There appears to be very generally diffused a mistaken idea on this point. Many people appear to think that a Provisional Order only lasts for 42 years, or 21 years under the old Act. This was stated in *The Times* the other day as a fact. It is, however, quite a mistake. The Orders granted by the Board of Trade, and confirmed by Parliament, have hitherto been, without exception, I think, unlimited in duration. There are various provisions for sale or transfer of the undertaking, including, in the case of a company, compulsory sale to the Local Authority; but these provisions may never be acted upon, and even if they are put in force do not extinguish the powers granted.

Section 6, with respect to regulations, is so important that it will be better to read the exact words—

6. *Regulations to be inserted in licences, &c.*—The undertakers shall be subject to such regulations and conditions as may be inserted in any licence, Order, or special Act affecting their undertaking with regard to the following matters:—

(*a.*) The limits within which and the conditions under which a supply of electricity is to be compulsory or permissive;

(*b.*) The securing a regular and efficient supply of electricity;

(*c.*) The securing the safety of the public from personal injury, or from fire or otherwise;

(*d.*) The limitation of the prices to be charged in respect of the supply of electricity;

(*e.*) The authorising inspection and inquiry from time to time by the Board of Trade and the Local Authority;

(*f.*) The enforcement of the due performance of the duties of the undertakers in relation to the supply of electricity by the imposition of penalties or otherwise, and the revocation of the licence, Order, or special Act where the undertakers have, in the opinion of the Board of Trade, practically failed to carry the powers granted to them into effect within a reasonable time, or discontinued the exercise of such powers; and

(*g.*) Generally with regard to any other matters in connection with the undertakings.

Provided always that the Board of Trade may, from time to time, make such regulations as they may think expedient for securing the safety of the public from personal injury or from fire or otherwise, and may from time to time amend or repeal any regulations which may be contained in any such licence, Order, or special Act in relation thereto; and any regulations so made or amended by the Board of Trade shall, from and after the date thereof, have the like effect in every respect as though they had been originally inserted in the licence, Order, or special Act authorising the undertaking; and every regulation so repealed shall, from and after the date thereof, be repealed accordingly, but such repeal shall not affect any liability or penalty incurred in respect thereof prior to the date of such repeal, or any proceeding or remedy which might have been had in relation thereto.

Any Local Authority within any part of whose district electricity is authorised to be supplied under any licence, Order, or special Act, may, in addition to any regulations which may be made under the preceding provisions of this section for securing the safety of the public, from time to time make, rescind, alter, or repeal bye-laws for further securing such safety; and there may be annexed to any breach of such bye-laws such penalties, to be recovered in a summary manner, as they may think necessary: Provided always, that no such bye-laws shall have any force or effect unless and until they have been confirmed by the Board of Trade and published in such manner as the Board of Trade may direct.

The proviso enabling the Board of Trade to make regulations from time to time, and to amend or repeal any regulations, is certainly a wise provision, and, as you are aware, it has been largely carried into effect. The power conferred upon the Local Authority of making bye-laws for further securing the safety of the public should also be noted, and that this may be exercised even where they are themselves the undertakers. In the case of Local Authorities being undertakers, power is given for them to contract for the execution and maintenance of any works, or for the whole business of supply; but they are forbidden to transfer or divest themselves of any legal powers or liabilities without the consent of the Board of Trade. As regards overhead wires, undertakers must get the express consent of the Local Authority for their erection along, over, or across any street, and the Local Authority may remove any electric line placed above ground without such consent, and, even where such consent has been given, a court of summary jurisdiction may order the removal of any electric line on the ground of public safety. It must be noticed, however, that nothing in this Act empowers any interference on the part of the Board of Trade or any other authority with electric lines erected by persons who are not undertakers. The undertakers are not allowed to prescribe any special form of lamp, or to interfere with the use made by any consumer of the supply given to him; but no consumer is to deal with his supply in such a manner as to unduly or improperly interfere with the supply to other consumers; and any dispute as to this may be be determined by arbitration. There are provisions against undue preference on the part of the undertakers in their supply and charges. I take the meaning of these sections (19) and (20) to be this—that the undertakers may make any agreement as regards price, hours of supply, &c., provided that the price is not in excess of the maximum rates laid down; but that, where they have made any such agreement with any private consumer, any other private consumer may demand a similar agreement, where the conditions are similar. And so in the case of street-lighting authorities; but not that a private consumer could demand to be supplied at the same rate as is agreed upon for the street lighting or for lighting a large theatre. Supply may be cut off for neglect of payment of charges due, but only until these charges and any expenses incurred in cutting off the supply are fully paid. Any unlawful and malicious injury of electric lines and works is made a felony, and any person who maliciously or fraudulently abstracts, causes to be wasted or diverted, consumes or uses, electric energy is declared to be guilty of simple larceny—in fact, to have stolen it. The purposes for which the officers of the undertakers may enter premises of consumers are strictly defined, and they have no legal right of entry for any other purpose—*e.g.*, to inspect the electric lines and fittings of the consumer. The Board of Trade has, however, so framed the Orders and Safety Regulations as to make it unlikely that any consumer would refuse entry to a properly authorised agent of the undertakers, if required by them to make an inspection of these electric lines and fittings. In the section of the Act providing for the protection of the Postmaster-General, it is curious to note that a distance of 10 yards was apparently considered as the outside limit of distance within which a telegraph line might be affected by an electric supply line.

The section dealing with compulsory purchase by the Local Authority after 21 years has been made the scapegoat for the failure of the electric lighting "boom" of 1883. It is questionable, however, whether it had so much effect as is attributed to it

* Paper read at the Institution of Electrical Engineers, on May 15, 1890.

Digitized by Google

in preventing capitalists from coming forward to support electric lighting schemes, and also whether whatever checking influence was really due to it has not in the long run been as beneficial as a nipping frost in early spring in restraining youthful impetuosity. And I may remark that this clause did not excite any serious opposition at the time; in fact, the Bill was sent up from the Commons with a fifteen years' limit, and extended in the Lords to 21 years, which was considered an ample time even by the persons best qualified to judge, as is amply demonstrated in the minutes of evidence given before the Parliamentary Committee.

In the amending Act of 1888 the first section has two important provisions:—

1. *Consent of Local Authority generally required to Provisional Order for Supply of Electricity.*—Notwithstanding anything in the Electric Lighting Act, 1882, no Provisional Order authorising the supply of electricity by any undertakers within the district of any Local Authority shall be granted by the Board of Trade except with the consent of such Local Authority, unless the Board of Trade, in any case in which the consent of such Local Authority is refused, are of opinion that, having regard to all the circumstances of the case, such consent ought to be dispensed with; and in such case they shall make a special report, stating the grounds upon which they have dispensed with such consent. The grant of authority to any undertakers to supply electricity within any area, whether granted by licence or by means of a Provisional Order, shall not in any way hinder or restrict the granting of a licence or Provisional Order to the Local Authority or to any other company or person within the same area.

The second section repeals Section 27 of the former Act, and substitutes 42 years for 21 as the time to elapse before compulsory purchase can be enforced. Section 3 gives power to the Board of Trade to vary the terms of compulsory sale in accordance with any agreement between the Local Authority and the undertakers. Section 4 is very important, as it empowers the Board of Trade to make regulations for the protection of the public safety and of telegraphic and telephonic lines in the case of any electric lines used for the supply of electric energy, however laid or erected, and whether under statutory powers or not. Perhaps I had better read the first part of this section—

4. *Restrictions as to Placing of Electric Lines, &c.*—(1). Where in any case any electric line or other work may have been laid down, or erected in, over, along, across, or under any street, for the purpose of supplying electricity, or may have been laid down or erected in any other position for such purpose in such a manner as not to be entirely enclosed within any building or buildings, or where any electric line or work so laid down or erected may be used for such purpose otherwise than under and subject to the provisions of a licence, Order, or special Act, the Board of Trade, if they think fit, may, by notice in writing under the hand of one of the secretaries or assistant secretaries of the Board of Trade, to be served upon the body or person owning or using or entitled to use such electric line or work, require that such electric line or work shall be continued and used only in accordance with such conditions and subject to such regulations for the protection of the public safety and of the electric lines and works of the Postmaster-General, and of other electric lines and works lawfully placed in any position and used for telegraphic communication, as the Board of Trade may by or in pursuance of such notice prescribe; and in case of non-compliance with the said regulations, then the Board of Trade may require such body or person to remove such electric line or work: Provided that nothing in this subsection shall apply to any electric line or work laid down or erected by any body or person for the supply of electricity generated upon any premises occupied by such body or person to any other part of such premises.

Sub-section (2) provides for the Postmaster-General taking action himself in the case of lines not laid under statutory powers, in the event of actual interference with his telegraphic lines, provided that these lines are not already regulated by the Board of Trade. The general purport of the section is to place the responsibility for the proper regulation of electric supply wires generally on the Board of Trade.

We now come to the dealings of the Board of Trade with the subject, and I propose to consider in the first place the various forms of Provisional Orders granted under the general Acts. As licences differ very slightly in form from Orders of the same date, it will not be necessary to discuss them.

There are up to the present time four forms of Orders, differing materially from each other in important respects, and showing, I consider, progressive improvement in the treatment of the subject as experience was gained. These are—1st. The 1883 form, of which Bradford is, I think, the only one now actually being worked, but some other Local Authorities are preparing to start under old Orders; 2nd. The Chelsea Order of 1886, and St. Austell licence of 1885; 3rd. The London Orders of last year, which form, I may point out, is only applicable to metropolitan districts under the London County Council; 4th. The model forms of Orders for this year, which were even now being modified in certain clauses and will not attain finality until some points have been determined by the action of Parliament. There are slight variations in form among individual Orders, generally due to some local considerations, and in every case there are considerable differences between Orders granted to Local Authorities and those granted to companies.

The first matter in all the Orders is the interpretation clause. In this, last year an innovation very important to electricians was introduced, viz., the definitions of "energy" and "power"—

The expression "energy" shall mean electrical energy; and for the purposes of applying the provisions of the principal Act to this Order electrical energy shall be deemed to be an agency within the meaning of electricity as defined in the Electric Lighting Act of 1882.

And—

The expression "power" shall mean electrical power, or the rate per unit of time at which energy is supplied.

They hang upon the definition of electricity in the principal Act as "electricity, electric current, or any like agency." Rather a general definition, you see. Now, the use of the term "energy" has, I consider, materially improved the language of the Orders, both from a scientific and a legal point of view. Under the old forms of Orders the undertakers were authorised to supply "electricity," and continual reference is made to this as the quantity supplied. Now, this word has, or had, many meanings, but in this case it could only mean electrical energy. But when we turn to the "Price" clauses we find that energy is expressly mentioned as differing from electricity, and that there, at all events, the latter meant what we now call "electrical quantity." There really was here some confusion of language, distressing to the electrician, and opening up grand possibilities of endless talk to lawyers. The proposed amendment was referred to your Council and concurred in by them, and I am glad to notice that the use of the term "electrical energy" is gradually working its way. I am not yet satisfied, however, with our word for what used to be the particular meaning of electricity. It is rather absurd to call it "electrical quantity," since so many other things are electrical quantities. I almost think we want a word for this even more urgently than for electrical locomotion, over which so much ingenuity has been lately expended. The worst of it is that, as nobody knows what it is, or to what extent its existence is an objective reality, it is difficult to find an appropriate word. At any rate, it was impossible in the Orders to call it "electricity" any longer, as the Act says that is what is to be supplied; so that we had to define "energy" as what was meant by electricity in the Act, and use "electrical quantity" for the particular meaning for want of a better word. This also necessitated an alteration in the title. There is a slight further alteration in the new model title.

As regards the definition of "power," this was necessary to avoid a difficulty in modifying a few clauses in the old Orders which dealt with the maximum current to any consumer to render them applicable to transformer systems. The definition of "main" has been materially altered. Thus it used to mean the conductor alone, then a continuous electric line, defined in the Act as follows:—

The expression "electric line" means a wire or wires, conductor, or other means used for the purpose of conveying, transmitting, or distributing electricity with any casing, coating, covering, tube, pipe, or insulator enclosing, surrounding, or supporting the same, or any part thereof, or any apparatus connected therewith for the purpose of conveying, transmitting, or distributing electricity or electric currents.

And, lastly, the word "continuous" has been omitted as unnecessary in the case of transformer system. The definition of "service line" has been altered in the same way. "Distributing main" has not been altered. It is a very important definition, which I will read—

The expression "distributing main" shall mean the portion of any main which is used for the purpose of giving origin to service lines for the purpose of general supply.

Difficulties may arise in interpreting this, as, for instance, in cases where the same conductor is at one part a feeder and at another a distributing main; but it is one of those things which must be left to custom and precedent.

The other definitions need not detain us now, except that two important ones have been added in the new forms—

The expression "consumer" shall mean any body or person supplied or entitled to be supplied with energy by the undertakers.

The expression "consumer's terminals" shall mean the ends of the electric lines situate upon any consumer's premises and belonging to him, at which the supply of energy is delivered from the service lines.

The consumer's terminals are the point of demarcation between the possessions of the undertakers and their customers; they need not be binding posts.

In the clauses headed "Area of Supply," an important novelty was introduced last year, and has been retained in the new model for companies, expressly prohibiting the undertakers from supplying outside the area granted to them without further statutory powers. This is a sacrifice of their common-law rights which they are required to make in consideration of the special privileges they acquire. You are perhaps aware that this provision is being carried out by mutual agreements between the London companies.

The old Orders, and the Liverpool and Swansea Orders of last year, provided for the division of the whole area into two districts, scheduled A and B respectively; the A district alone being the

Digitized by Google

area for which powers are immediately granted, and in which supply is compulsory; while the B district was intended to be added piece by piece, practically at the option of the undertakers. The general effect of this was to induce undertakers to apply for very large districts, the greater part of which were in the B schedules, over which they thereby acquired a sort of prior right of occupation without incurring any liability. This was altered last year and a single district substituted, to the whole of which the "Compulsory Works'" clauses apply.

Nature and Mode of Supply.

In the old Orders two systems were mentioned, viz., the "parallel system," and the "series system," meaning constant-pressure and constant-current systems respectively. Now, no system is specified, except that it must be one approved by the Board of Trade. A new sub-section was added to this last year at the instance of the telephone companies, by agreement with the promoters, for the protection of the telephone circuits against interference by induction or otherwise, they being naturally rather alarmed at the proposed general use of alternating currents.

In the "Works" clauses, I need only mention that in the new model it is proposed to give powers for the construction of "street" boxes in place of "distributing" boxes. The special power taken is necessary, I believe, because these boxes come up to, and may come above, the surface of the ground. Also, that the prohibition of overhead wires, introduced last year, is inserted in the new model for companies, with the alteration that the time allowed for removal of existing overhead wires is reduced to one year. But they may be erected or continued in use with the consent of the Local Authority. This prohibitory section is based upon, and really does not go beyond, section 14 of the Act of 1882.

The "Compulsory Works" clauses provide generally that the undertakers shall do something substantial towards carrying out their undertaking within a specified time, under penalties of fine or revocation of the Orders. The Board of Trade, however, must, in the case of a company, be moved to exercise its power of revocation by the Local Authority, except in the last model, where this has been altered; while in the case of a Local Authority being the undertakers, the Board of Trade has not hitherto, so far as I am aware, thought fit to exercise its power of revocation for non-performance of works within the required time, probably considering the plea that the practical knowledge and experience of electrical distribution was not sufficient to justify any expenditure of public funds, a valid one. This plea, however, is obviously daily diminishing in force. In nearly all Orders the specified time within which mains have to be laid in certain streets is two years. It is three years in the Birmingham Order of last year, but all streets within the area are included. The Liverpool Order is also an exception.

In the old Orders two years was also the period that had to elapse before any supply could be requisitioned in other streets, and six months more is allowed to comply with the requisition. In last year's London Orders and the new forms, however, supply can be requisitioned after eighteen months, with six months for compliance; so that persons in streets not scheduled can get a supply at the same time as those in scheduled streets. Also, in the recent Orders, as already mentioned, supply can be requisitioned for any part of the area included in the Order; whereas in the old Orders it could only be requisitioned for the A district. There is a slight variation, too, in wording, which may be important, viz.: whereas in the old Orders mains were to be laid *in* every street, now it is *throughout* every street.

The requisition to lay distributing mains in any street has to be signed by a number of persons, which number is a very variable quantity in different Orders. Thus in the old Orders of 1883 it was two or more owners or occupiers in the case of an Order given to a company or person, and the owners or occupiers of not less than one-fourth of the premises in the street in the case of a Local Authority. In the Chelsea Order of 1886 it was six or more owners or occupiers. Last year the Board of Trade reverted to the former practice both in the case of companies and Local Authorities, except in the Birmingham and Liverpool Orders, where no power of requisitioning is given to owners. These two Orders are very exceptional in respect of these clauses. This year, in the model forms, which are not intended to apply to London, it is proposed to follow the precedent of the Chelsea Order, and to require six signatures to a requisition, the number being the same both for Local Authority and company Orders.

After the requisition clause follows a long clause intended to provide that the undertakers shall, if they so require, be guaranteed by the persons making the requisition a return for their outlay in laying the requisite mains of 20 per cent. per annum for three years in the old Orders, two years in the London Orders, and again three years in the new model Orders.

After these "Compulsory Works" clauses come a few clauses headed "Maps;" and then, in the old Orders, "Regulations as to Supply on the Parallel System." These regulations are not inserted in any of the recent Orders, but are issued separately with the Safety Regulations. Then we come to some clauses headed "Testing" in all Orders up to this year; but in the new models an improved arrangement has been followed, and "Supply" comes next to "Works," which certainly seems a more logical sequence; also, the clauses applying to the appointment and duties of electric inspectors are now put under a separate heading.

Taking these clauses first, the appointment of electric inspectors is vested, in the case of all Orders to companies, except the London Orders, in the Local Authority; in the London Orders it is vested in the County Council; and in all existing Local Authority Orders in a court of summary jurisdiction, moved either by a consumer or by the undertakers themselves. In the new model this appointment is vested in the Board of Trade. In case of the Local Authority not appointing an inspector, or imperfectly attending to inspectional duties, there is a provision in all company Orders for appointment, in some cases by a magistrate, in others by the Board of Trade.

In the new model Orders a clause has been added specifically stating that the Board of Trade may appoint an inspector for the purposes of any inquiry on an accident or as to safety. I think it is obvious that the Board of Trade has in any case, whether expressed in the Order or not, the right to make inquiry as regards safety.

All local inspectors are to be paid by the Local Authority, or County Council for London; but fees may be charged by means of which part, at any rate, of the cost of inspection will be recouped. Inspectors may be appointed from time to time for particular services, or the appointment may be continuous. It is rather difficult to see how this matter will work in small towns where there may be no resident electrician unconnected with the undertakers, or, at any rate, none who would care to undertake the job for such remuneration as could be offered without unduly increasing the cost of the supply, since the expenses of inspection must in one way or another be borne by the consumers. Probably one electrician will secure the appointment for several towns not very far apart, and reside in a convenient locality for his district. It will be something like the birth of a new species; and some follower of Darwin will in the next century write an exhaustive monograph on the genesis of the electric inspector, showing how he came to differentiate from ordinary mortals, how he gradually acquired an extra sense warning him against high pressure, &c.

The duties of electric inspectors are clearly defined in the new model Orders, as follows:—

> The duties of an electric inspector under this Order shall be as follows:
> (*a*) The inspection and testing, periodically and in special cases, of the undertakers' electric lines and works and the supply of energy given by them;
> (*b*) The certifying and examination of meters; and
> (*c*) Such other duties in relation to the undertaking as may be required of him under the provisions of this Order or of any regulations under this Order.

The next clauses in the new models are headed "Testing and Inspection;" and this is an improvement on the old heading of "Testing" alone, since it is obvious that in the case of a network of mains a good deal may be found out by inspection that could hardly be arrived at by testing. These clauses have been greatly altered, and I would especially draw attention to a new clause—

> 40. *Testing of Works and Supply on Consumer's Premises.*—An electric inspector, if and when required to do so by any consumer, shall from time to time, on payment by the consumer of the prescribed fee, test the variation of electric pressure at the consumer's terminals, or make such other inspection and testing of the service lines, apparatus, and works of the undertakers upon the consumer's premises as may be necessary for the purpose of determining whether the undertakers have complied with the provisions of this Order, and the regulations and conditions subject to which they are for the time being authorised to supply energy.

Which is, I think, very practical, and may have important results. This clause takes the place of the following in the existing Orders:—

> 35. *Testing of Service Lines.*—Every electric inspector, if and when required to do so by any person supplied with energy by the undertakers, shall from time to time test for insulation and conductivity any service lines by which such energy is supplied and the efficiency of any joints in such service lines, and make such other tests in relation to such service lines as may from time to time be approved of by the Board of Trade.

In all Orders there is a clause providing for the establishment of testing stations at various points in the area, either by the undertakers or by the Local Authority. I am not aware that any such testing stations have yet been established; but I believe that in several districts in London they are to be established for one position, at any rate—at the office of the Local Authority. The practical use of these testing stations is obviously to obtain a record of the variations of pressure at different points in the system, and of the duration of any abnormal pressure or stoppage of supply. The best solution appears to be to have a recording voltmeter at

Digitized by Google

each station, which might be made in the shape of a pillar box; and possibly an indicating voltmeter exhibiting the pressure at any time would be a welcome addition. I consider that the production of a thoroughly trustworthy recording voltmeter is distinctly a desideratum for the improvement of electric supply. There appear to be very few such instruments in use at the present time.

In all Orders I think there is reserved an appeal to the Board of Trade against any report of any electric inspector. It is to be hoped that this power will be used with discretion, as the electrical staff of the Board of Trade is strictly limited at present.

Now, taking the "Supply" clauses, we have, first, that any owner or occupier of premises situated within a certain distance of any district main can demand a supply. This distance is in the 1883 Orders 25 yards; in the London Orders and the new forms, 50 yards. He may be required, however, to pay the cost of service lines beyond a distance of 30ft. in the old, 60ft. in the London and new model Orders. He must name a maximum current in the old Orders, or a maximum power in the new, so that the proper size of service lines may be laid, and this maximum must not be larger than what may reasonably be expected to be the consumption on the premises; and if afterwards he wishes to go beyond the declared maximum, he must be prepared to pay for any alteration of service lines or apparatus thereby rendered necessary. The person requiring a supply must also be prepared to make a contract to take and pay for a supply for at least two years of sufficient amount to pay 20 per cent. on the outlay incurred by the undertakers. Then follow provisos as regards security for payment, prohibition of improper use of the supply, and a very important one added last year, which I will read. The "Price" clauses have been considerably affected by the supply being now considered a supply of energy, and not, as formerly, of electricity. I will read the first clause as it stood in the old Orders and in the London Orders:—

31. *Price.*—The undertakers may charge for electricity supplied by them to any consumer (otherwise than by agreement)—(1) By the quantity of energy contained in such supply; or (2) By the actual quantity of electricity so supplied; or, unless the Board of Trade from time to time otherwise direct; (3) By the number of hours during which the supply of electricity is actually used by such consumer, and the maximum current with which he is for the time being entitled to be supplied.

50. *Methods of Charging.*—The undertakers may charge for energy supplied by them to any ordinary consumer (otherwise than by agreement) —(1) By the actual quantity of energy so supplied; or (2) By the electrical quantity contained in such supply; or, unless the Board of Trade from time to time otherwise direct; (3) By the number of hours during which the supply of energy is actually used by such consumer, and the maximum power with which he is for the time being entitled to be supplied.

In the new models method (3) has been altered as follows:—

32. *Methods of Charging,*—The undertakers may charge for energy supplied by them to any ordinary consumer (otherwise than by agreement)—

(1.) By the actual amount of energy so supplied; or,
(2.) By the electrical quantity contained in such supply; or,
(3.) By such other methods as may for the time being be approved by the Board of Trade.

The reason for this is that the old method (3) is decidedly wasteful, and, if generally adopted, would lead to far more energy than was necessary being supplied from central stations. Except in special cases, such as lighting of shops and business premises, it should be noted that the consumers are free to make any agreement they prefer as to the price to be charged and the method, but they have a right to be charged in accordance with methods (1) or (2), and the undertakers are always bound by the undue preference clause.

The meter clauses have hardly been altered at all, and it is, in my opinion, proof of the very great care and acumen with which these clauses were originally drawn, so far back as the year 1883, that no really satisfactory improvement has yet been proposed. These clauses will repay very attentive study. They are sometimes looked upon as stumbling-blocks, and it is said that they are unintelligible, and that they won't work; but I am afraid that these difficulties are rather due to want of study and defects of meters than to the clauses themselves. They are too long to take in detail, but, roughly, the gist is as follows:—

Any number and description of meters may be used both by consumer and undertakers, but only one meter is to be used for ascertaining the value of the supply. This is to be a meter certified by an electric inspector appointed under the Order. Note that it cannot be certified by anyone else. The inspector must certify three things—(1st) That the meter is of some construction and pattern approved by the Board of Trade; (2nd) That it has been fixed and connected to the service lines in some manner approved by the Board of Trade, which must, therefore, in approving any pattern of meter, prescribe in what way it is to be fixed and connected to the service lines; (3rd) That it is a correct meter; and in making this last declaration the inspector, in my opinion, may reasonably take account of and be guided by any mark or certificate attached to the meter showing that it has been thoroughly tested and found sufficiently accurate to be pronounced a correct meter in some standardising laboratory, or he may himself carry out the necessary tests in a laboratory. It is obvious that he cannot thoroughly test it in the consumer's cellar, and also that the words "a correct meter" cannot be held to be only applicable to a meter that was absolutely perfect throughout its range. The undertakers are to supply the consumer, either by purchase or hire, with a meter on demand, and procure its certification. No consumer is allowed to connect or disconnect the meter used for ascertaining the value of the supply without giving 48 hours' notice to the undertakers, under penalty. If this meter belongs to the consumer, he is to keep it in proper order, but if it is hired from the undertakers they must maintain it; and in either case they may remove it for testing, all expenses connected with the removal being paid by the consumer if the meter turns out to be faulty, and by the undertakers if it is in proper order; and any other meter or apparatus placed by the undertakers upon the sumer's premises for the purpose of ascertaining or regulating the supply of energy must be of some construction and pattern and connected in a manner approved by the Board of Trade.

The only other point in the Orders of much electrical interest is the Price Schedule. In this the definition of the Board of Trade unit has remained unaltered, except the simplification of the wording. Last year there was, as you may remember, some agitation to have the amount of the unit increased tenfold. The point was referred to your Council, who did not recommend the alteration, and the Board of Trade very willingly left it as it was. Of course, undertakers are at liberty to make agreements for a price per 10 units, provided that the charges do not exceed the rates laid down in this schedule.

In the London Orders of last year there was added to the second section a proviso to enable the standard pressure on the mains to be taken into account in assessing the value of the supply where this pressure is a high pressure, and the energy is transformed; but in the new model this section has been much simplified by the introduction of a new term, viz., the declared pressure at the consumer's terminals, which it is proposed to deal with in the new regulations.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, June 6th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1). "The Effect of Change of Temperature on the Villari Critical Point of Iron." By HERBERT TOMLINSON, F.R.S. (2). "The Diurnal Variation of the Magnet at Kew." By W. G. ROBSON and S. W. J. SMITH.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Search for Coal in the South of England." By Prof. W. BOYD DAWKINS, F.R.S.

SATURDAY, June 7th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Ballad Music of the West of England." By the Rev. S. BARING-GOULD, M.A.

TUESDAY, June 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Natural History of Society." By ANDREW LANG.

THURSDAY, June 12th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Flame and Explosives." By Prof. DEWAR, F.R.S.

SOCIETY OF ARTS.

5 p.m. Indian Section: "The Rationale of Indian Railways." By Sir THEODORE C. HOPE, K.C.S.I.

FRIDAY, June 13th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Physical Foundation of Music." By Prof. SILVANUS P. THOMPSON, D.Sc.

SATURDAY, June 14th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Ballad Music of the West of England." By the Rev. S. BARING-GOULD, M.A.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and be crossed* "*Coutts and Co.*"

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

THE PHYSIOLOGICAL EFFECT OF ELECTRIC CURRENTS.

A subject of great importance in connection with the rival merits of alternating and continuous currents is their physiological effect upon the human body. The great difficulty of finding a method of test which shall be beyond criticism is, no doubt, mainly responsible for the fact that comparatively little time has yet been spent on such investigations. It is, however, a matter of universal interest to ascertain how far it is necessary to adopt greater precautions to avoid danger when alternating potentials are used, than when direct ones are employed; and experiments with this object in view are accordingly much to be desired, even if the results obtained require subsequent modification. Contributions from the medical side are of special value, and for this reason the recent Paper of Messrs. LAWRENCE and HARRIES has done good service in emphasising the physiological aspect of the question. Electricians are, perhaps, somewhat inclined to treat the human body as an inanimate conductor; and it is, therefore, opportune to point out the great distinction which must be drawn between the resistance presented by the body to the flow of an electric current, and the sensation of discomfort produced by its passage.

If the title of their Paper had been less comprehensive there would be nothing but praise to bestow on its authors, recording as it does the results of many interesting experiments; but the words "alternating v. continuous currents" cannot but call to mind a controversy with which the tests in question have little to do; and the only legitimate conclusion which can be drawn from the sensational danger ratios given by the authors is, that their experiments can have little

Digitized by Google

bearing on the practical points at issue, since the results asserted are quite at variance with actual experience. It is, indeed, unfortunate that the results of the experiments were embodied in a form so ambitious as is indicated by the word *danger-ratio*, for only a most comprehensive research could justify such a course. It is not surprising, considering the importance of the question, and the anomalous nature of the results, that the Paper should have provoked considerable criticism; and our correspondence columns have indeed recently contained several reasons for modifying the conclusions drawn.

As we have already hinted, it is practically impossible to make tests of this kind in a manner which is not open to objection, however great may be the care bestowed on the actual experiments. The measurements of resistance must be accepted with considerable caution. When intermittent or alternating currents are employed the self-induction of the resistance coils in the bridge and the capacity of the human body would each tend to make the resistance appear less than for direct currents, especially with so high a frequency as 300 per second. An excellent instance of the misleading results it is possible to obtain under somewhat different circumstances, unless great precautions are adopted, is given in the letter of Mr. Otto T. Bláthy. It is here stated that the resistance of his assistant when grasping two stout copper electrodes was found to be between 4,000 and 5,000 ohms for both direct and alternating currents, the testing potential used being 30 volts in the former, and 15 volts, alternating at 50 periods per second, in the latter case. This was when a Wheatstone bridge specially arranged so as to be devoid of self-induction was employed. When, however, a large Elliott bridge was used, with a potential of only 8 volts, the same assistant presented a resistance of 15,000 ohms. This experiment sufficiently indicates the importance of self-induction, but it shows in addition the influence of the testing potential on the results obtained. The fact that the potentials employed by Messrs. Lawrence and Harries were not the same when direct and intermittent currents were used is alone sufficient to render the comparison unfair; and if the true resistance of the human body to direct and alternating currents really differs in consequence of properties peculiar to living organisms, it is none the less necessary to perform the different tests under comparable conditions. The smallness of the potentials used in the tests, compared with those common in practice, gives weight to an objection of Mr. Kennelly, who has cast doubt on the measurements because the effects of polarisation are included in the values given for the resistance. No doubt, as Mr. Lawrence points out, it is the apparent resistance which determines the danger ratio, since the true resistance and the spurious resistance due to polarisation act together in preventing the passage of electricity through the body. As, however, the relative importance of these factors will vary considerably with the potentials employed, it is obvious that no certain conclusions with reference to practice can be drawn from experiments made with potentials differing widely from those actually in use.

It is, however, in connection with the sensation tests that there is most need to take exception to the results. Mr. Sayers has drawn attention to an important inference which the experiments suggest. It would appear that, under conditions of contact which are intended to reproduce those occurring in practice, it only needs a little over six volts to produce muscular fixation when intermittent currents are employed. Whether or not it is reasonable to suppose that 10 times this potential should produce death, the ratio of the potential actually required to kill to that needed to bring about muscular fixation, certainly seems, according to these experiments, incredibly high. The main reason for the unexpected character of the results is, in all probability, that pointed out by Prof. Forbes. The intermittent currents given by the induction coil differ very widely from the alternating currents known to electrical engineers. While, with the latter, the maximum current is only about half as large again as the mean, with the former the maximum current rises to many times the effective current. The measuring instruments employed indicated the average current; and we have only to assume that the sensation of discomfort is due to the maximum value of the current to sufficiently account for the great divergence of the danger ratio given from that which practical experience indicates. The truth of this explanation can readily be tested by repeating the resistance and sensation measurements when the alternating currents employed are of the usual harmonic type. It may even be possible to obtain differences in the measurements by simply altering the adjustment of the vibrating contact maker of the induction coil.

A valuable contribution to our knowledge of the physiological effects of electric currents has recently been published by Dr. Edward Tatum, and a brief description in our American Notes of his experiments will be found in *The Electrician* of the 23rd May. Dogs, not human beings, were the individuals tested; but, on the other hand, the currents used were such as to produce death; so that the experiments are perhaps more applicable to the important question at issue than others in which only feeble currents are employed. A most important conclusion arrived at is, that the action of the current is something more than an action on the nerves. With dogs, at all events, the chief mischief is due to an action on the heart, although both brain and heart are affected. It was found that the mean value of an alternating current need only be of about half the value of a direct current to produce the same deadly effect. When, however, the dogs were etherised, and rendered insensible to nerve action, no difference whatever was detected between the fatal powers of continuous and rapidly alternating currents. Dr. Tatum very forcibly concludes that, as currents may be fatal when all sensibility to pain has been abolished, and when there is no discoverable action on the nerves or muscles, we have no right to gauge the fatal powers of different kinds of currents by their relative capacities for exciting muscular contraction, or sensations of pain. The currents that have greater killing powers can only be found out by direct experiments with currents that kill.

THE DUNCAN MULTIPOLAR MOTOR.

We are indebted to the *Electrical Engineer* of New York for the following particulars with regard to the multipolar slow-speed motor recently designed by Dr. Louis Duncan, of Johns Hopkins University. This machine was briefly referred to by our New York correspondent in our issue of May 30th.

In Fig. 1 we have the motor in perspective and partly in section, and it will be seen to consist of an armature C, which is centred on the shaft A, and which is under the inductive action of the magnets N S, the form of which is more clearly shown in Fig. 2. These consist of a cylindrical portion which is shrunk on the shaft and have polar projections bent so that their inner surfaces form right angles enclosing the armature, and so arranged that the ends of the projections on the one side are midway between the projections on the other side. The illustration shows the armature having 28 polar projections, 14 on each side. The essential feature is that the polar projections of one polarity on one side are opposite the spaces between those of opposite polarity on the other side and fewer by some even number than the

Digitized by Google

coils on the armature, the object of which will be described presently.

In the machine illustrated the field magnets revolve and are attached to the shaft, A, which it drives. The armature C is stationary, being held fast by the lugs shown. The armature is a ring similar in form to the well-known Pacinotti or Gramme ring, but differing essentially as to the method of winding. In a motor having 28 polar projections, as the one illustrated, it has 30 coils surrounding it, the adjacent coils being wound in opposite directions instead of all being in the same direction, as in a Gramme ring. This is shown in Fig. 2, there being a wire taken from the junction of the adjacent coils *d d'* to one bar of a 30-part commutator, as in the ordinary Gramme armature.

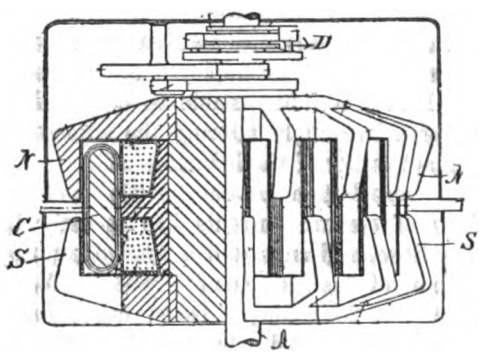

FIG. 1.

The commutator may be stationary, as shown in Fig. 1, or revolve. In the former case the brush holder is revolved by a series of gear-wheels, so that the brushes make fourteen revolutions for every revolution of the magnets. In another form of commutator there are 420 segments, forming the commutator-bars, divided into 28 groups of 15 segments each. It will be observed that there are one-half as many segments on the commutator as results from the multiplication of the number of polar projections by the number of coils on the armature. In this case the commutator turns with the motor shaft.

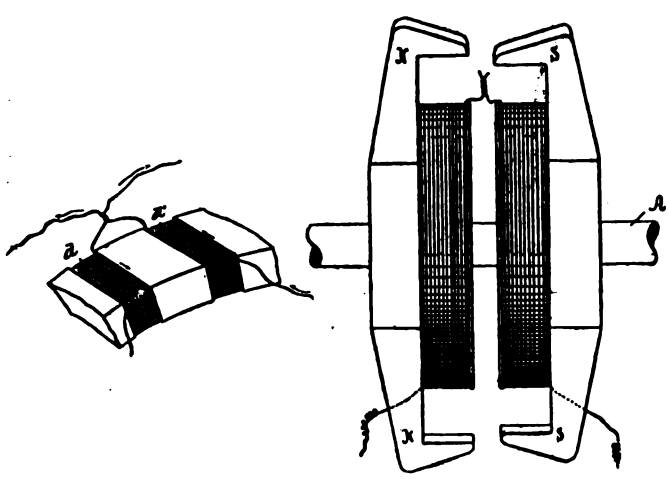

FIG. 2.

When the current passes through the armature all the teeth of the armature are energized excepting those between the pairs of coils on opposite sides of the armature in connection with the brushes. These portions, by reason of the direction of the current and the windings of the coils, are not energized. The connections of the brushes are so arranged that when the current enters these coils the teeth between them are exactly opposite the polar projections of the field-magnet. When the commutator has moved through $\frac{1}{420}$th of a revolution, the teeth between the succeeding coils will be exactly opposite the succeeding polar projections. The same instant the brushes pass upon the succeeding segments of the commutator. These segments are divided into groups of 15 each, and it is so provided that all the segments of each group send the current in the same direction, and also that each succeeding group of segments shall change the direction of the current. It is evident that there will be 28 changes of the current at each revolution of the commutator—a number corresponding to the number of polar projections in the field-magnet.

The result of this arrangement is a steady continuous pull at the periphery of the armature, which permits of obtaining a high efficiency at a comparatively slow speed.

LEGAL INTELLIGENCE.

King, Brown and Co., v. The Anglo-American Brush Electric Light Corporation.

The discussion in the reclaiming note against Lord Trayner's judgment in the action King, Brown and Co., Edinburgh, v. The Anglo-American Brush Electric Light Corporation, was resumed in the First Division of the Court of Session, Edinburgh, on Thursday last week.

Mr. JAMESON, for the Brush Company, continued his speech. He proceeded to contend that the segment T was meant to be a conductor as well as an insulator, and was more mechanical than anything else. Lord Trayner, in his judgment, admitted that as a mechanical arrangement it was new and useful, and not open to challenge. "But," his lordship proceeded, "the pursuers maintain that the letters patent under reduction are rendered invalid by reason of the patentee claiming in his final specification (as amended and described) something with reference to the commutator as an invention which is not foreshadowed in the provisional specification. The claim here referred to is the fourth, which is in these terms:—'The commutator having metallic insulating segments substantially as shown in division three.' It appears to be necessary, or at least desirable and advantageous, to cut the armature bobbins out of circuit T, when they are crossing the neutral or current-reversing points of the magnetic field. To do this the continuity of the current-conducting segments of the commutator has to be broken either by a mere space or by the insertion of some non-conducting material at the given point. The cutting of the bobbins out of circuit was known and practised before the defenders' patent, but it was not before then done by means of an insulating metal segment. The advantage which attaches to the defenders' method is this, that the insulating segment being metal, like the conducting segments, there is insured a certain uniformity of wear over the entire surface of the commutator, which could not be preserved where a softer material was used, or where merely a space was left. I am not aware that prior to the defenders' patent any insulating body, metal or otherwise, was ever used in the construction of the commutator, for the purpose of cutting the bobbins out of circuit. The insulating segment T of the defenders' patent was therefore a novelty, and its utility I do not understand to be disputed. But was it foreshadowed by the provisional specification? I think not. In the first place the defenders' second claim seems to me to be co-extensive with the provisional specification (in so far as it relates to the commutator) so that there was nothing left to claim under another head. If all that was foreshadowed in the provisional specification is included in the second claim, then the fourth claim, unless regarded as mere repetition, which nobody suggests, is for something not there foreshadowed. Secondly, the provisional specification relates only to the construction of a cylindrical commutator, whereas one of the chief purposes of and one of the main advantages to be derived from the insulating segment T, is the preservation or maintenance of the cylindricity of the commutator, an object probably as important and as patentable as—but quite distinct from—the shape or mode of construction. Thirdly, the insulating segment T is not merely or necessarily a part of the cylindrical commutator having sub-segments with wearing segments detachably attached. It has, and is intended to have, a peculiar function, which is not referred to in the provisional specification at all. Fourthly, it is said that the segment T is a part of the wearing segment, and therefore falls within the description of the provisional specification; but I think this is not so. The wearing segment is an essential part of the defenders' commutator, the segment T is not. It may be dispensed with altogether. I come, therefore, on this part of the case, to the conclusion that the patent sought to be reduced is invalid, in respect that the invention claimed in the final specification is larger and different from that claimed in the provisional specification." Now, Mr. Jameson proceeded, in the specification Mr. Brush desired it to be understood that the insulator T need not of necessity be material. It was really a wrong construction of the patent altogether to take up this opinion in order to avoid their claim as to this insulator T, because Mr. Brush did not claim the hub in which the T did not occur. But for the sake of publication he said "that if anybody liked to construct a commutator like mine having the other elements or integers of my invention, but chooses to leave out the segment T; or to substitute for it a wooden segment, or something of the sort, he might do so if he chose." Mr. Brush secured by that that his invention should not be pirated. He did not claim the insulator T; and it was an extraordinary construction of the patent to say that after having given notice of this to the world generally he was to be held as invalidating his own claim for T altogether. He quoted the evidence of Prof. Perry, Sir William Thomson, Mr. Brush, and Mr. Imray, and said that of course there were two views taken by witnesses upon the point; but he submitted that the sound view, taking

Digitized by Google

that explanation as to the effect of the arrangement, was that Brush showed he intended to construct cylindrical commutators. Certainly he meant commutators which were cylindrical, and which would preserve their cylindrical form by the various devices which he set forth. He thought that matter was really disposed of when one considered the objects of a provisional specification. Chief Justice Boyle said that "the object of a provisional specification was only to describe generally and fairly the nature of the invention, and not to enter into all the minute details as to the manner in which it was carried out. Otherwise a provisional specification would require to be a full and complete specification. The statute itself clearly indicated the distinction, because it called the latter a complete specification, implying that the former was in some respects incomplete. Moreover, it indicated that a provisional specification was to describe the nature of the invention and no more." Now, this was a description of a cylindrical commutator with an insulating hub and metallic sub-segments placed in connection with the general mechanism, and metallic wearing segments detachably attached to said sub-segments. Now, these were metallic segments in all cases in which the claim was made. No doubt the inventor said he might dispense with part of his wearing segments, but that was plainly an invention.

Mr. GRAHAM MURRAY: I may say that I do not think there is anything between us in the law. All that a provisional specification may do is to disclose the nature of the inventions. But then if I can show that the final specification has got a different invention in it from the one in the completed specification, then the patent is invalid.

Mr. JAMESON said they submitted that every item of all these claims carrying out the construction of a cylindrical commutator, with an insulating hub and metallic subsegments and wearing-segments, was clearly enough foreshadowed in the provisional specification. It did not matter if in perfecting that invention they said that some wearing segments might be attached to others in the adjoining part of the cylinder, or that part of the wearing segments might be so arranged as to cut out the bobbins. They did not claim as an invention the cutting out of bobbins, but they were claiming the invention of a commutator which was to be used in connection with a machine otherwise described, in which the cutting out of the bobbins was an object to be attained. Therefore, they adapted that mechanical appliance to the machine in which they are to use it, but they did not claim the cutting out of the bobbins, but simply claimed a cylindrical commutator, and they introduced a certain form into it—these wearing segments—so as to meet the cylindrical requirements of the machine. That being so, he submitted they were fairly within the provisional specification, and that it would be altogether too stringent a construction of the provisional specification to say that it did not fairly cover everything that was claimed in the completed specification. That concluded what he had to say upon the point of the commutators. He now came to the much larger and more important question, he thought, in every sense of the word—the question of the series-shunt winding. There were a number of anticipations alleged upon record, but they were all narrowed down to the anticipation by that publication contained in Varley's specification, and the alleged public user by Varley's machine. Therefore, he might confine their attention to an investigation into Varley's specification, 4,905 of 1876.

LORD McLAREN: I suppose if Varley's specification be actually an anticipation, it is not necessary to prove that the design there described was for use.

Mr. JAMESON: No; publication is sufficient; but then, he added, the law which had already been laid before the Bench came in that for a completed specification there must be such a description as will enable a workman of ordinary skill to make a machine of the kind described; and they must remember in that particular investigation that they must not take a skilled workman of the present day, but a workman of ordinary skill of 1876, when Varley's specification was published. They must also bear in mind that if there were publication here, and that most important invention lay open to everybody, nothing was done from that day to this except to make that particular machine, which was made upon Varley's own orders in the works of Siebe and Gorman, who were Varley's partners.

The LORD PRESIDENT: Suppose Varley's invention was only disclosed in the provisional specification; if that was earlier in date than yours, then you are not the person who first invented it.

Mr. JAMESON: That would be so.

The LORD PRESIDENT: It does not require a complete specification.

Mr. JAMESON: It is a complete specification, but I say it was not sufficient to enable a workman to make it.

The LORD PRESIDENT: Suppose it is complete. If that specification discloses fully the nature of the invention, but does not sufficiently describe the method in which it is to be made to enable a workman of ordinary skill to make it, still you would not be the true inventor.

Mr. JAMESON: I think in law we would be entitled to the patent.

The LORD PRESIDENT: I do not think that.

Mr. JAMESON: Unless he published and used it,

The LORD PRESIDENT: He published it in the specification.

Mr. JAMESON: But it must be publication such as would enable a workman of ordinary skill to make it.

The LORD PRESIDENT: No. It is publication of the invention that would be an anticipation of yours, although there is no description of how it is to be carried out.

Mr. JAMESON: I shall consider that point. I am not prepared at present to meet it.

The LORD PRESIDENT: I am afraid that is the law.

Mr. JAMESON: A patent was really founded upon this principle, that every person who made an invention and got a patent for it should so describe it as that the invention shall be useful to the public.

The LORD PRESIDENT: That is essential to the validity of his patent, but he may be the first inventor although he has not got a good patent.

LORD McLAREN: Suppose a man had described a patent in his specification without giving details, would not that be a good patent?

Mr. JAMESON: Not unless it shows enough to enable a workman of ordinary skill to make it.

The LORD PRESIDENT: I do not think that. Suppose a man had described an invention in a magazine which was read by the public?

Mr. JAMESON: That would be a different question. We are here upon a specification, and upon nothing else. If persons are to get advantage of the publication in the specification that must be complete.

The LORD PRESIDENT: What is your authority for that?

Mr. JAMESON: I shall endeavour to get that authority at a later stage.

The LORD PRESIDENT: There are many cases in which a man has lost his patent through defects in the specification, but he did not cease to be the inventor of the machine; and the question here is, whether you or Varley was the first or true inventor?

Mr. JAMESON: Certainly. And we say that not only is there that wanting in the specification, but really that Varley himself did not understand or invent this.

The LORD PRESIDENT: That you are quite entitled to try to make out.

Mr. JAMESON said that at the time of Varley's specification in 1876 there had only been series and shunt-winding, the machines then having separate modes of excitation, either inside or outside, drawn from a separate source. Shunt-winding was hardly known. It had only been spoken of in the communication by Sir Charles Wheatstone, and that was in 1867, but that was hardly shunt-winding. It was shunt in a fashion, but it might quite as well have been described as a short-circuit series machine. But in 1879 Sir Wm. Siemens took out a patent for shunt. That was the first time a patent was taken out for a shunt except by Brush, who afterwards disclaimed it in consequence of this communication by Wheatstone to the Royal Society. Therefore in 1879 they had it in evidence that the shunt arrangement was not likely to be known to the world. The first time shunt machines were exhibited and were commercially successful was in 1881. They were shown at the Exhibition in that year, and came into general use. Now, he asked their lordships to turn to Varley's specification. They might take it as admitted that Brush's specification clearly and distinctly set forth this compound winding. Their claim was, "In a dynamo-electric machine the wire or helix E having a comparatively high resistance and kept in close circuit while the machine is running in combination with the magnetic wire or helix F as commonly employed, substantially as shown in division four." In his specification Haddan said, "My invention has for its object the maintenance in dynamo-electric machines of a 'magnetic field' while the machine is running, whether the external circuit is closed or open. In dynamo-electric machines as ordinarily constructed no magnetic field is maintained when the external circuit is opened except that due to residual magnetism; hence the electromotive force developed by the machine in this condition is very feeble. It is only when the external circuit is closed through a resistance not too large that powerful currents are developed, owing to the strong magnetic field produced by the circulation of the currents themselves around the field-magnets. Such machines are not well adapted to certain kinds of work, notably, that of electro-plating. I attain my object by diverting from external work a portion of the current of the machine, and using it either alone or in connection with the rest of the current for working the field-magnets." Now, turning to Varley's specification, Varley states, "This invention is an improvement on a previous invention, for which provisional protection was granted to myself in conjunction with Cromwell Varley, bearing date December 24, 1866, but which was not proceeded with, and which invention was made the subject of a second application, and for which letters patent were granted to us, bearing date June 15, 1867." Varley then went on to state that in the previous provisional specification a method was described which might be said to have marked a new era in the construction of dynamo-electric machines used for producing the electric light. Nearly all the subsequent machines, Varley proceeded, which had been designed for this purpose depended for their action on the principle first described in the provisional specification. This principle consisted in causing electricity and magnetism developed by the expenditure of mechanical force to act and react on one another in the machine itself, in such a way as to develope a greatly increased amount of both these forces. Such increased amount of magnetism and electricity, as was well understood, involved an increase in the consumption of mechanical force for giving motion to the machine. The development of electricity and magnetism, such as Varley described, Mr. Jameson contended, was not at all the development which took place by winding coils to the magnets with wires, through which the electric current was running, thereby increasing the magnetism. Mr. Varley said that his improvement consisted in separating the development of the electrical and magnetic forces to a considerable extent, obtaining thereby greatly increased magnetic potential in the bobbins, which, at a later stage, became converted into electricity of a correspondingly high potential. He effected this by what might be described as splitting up the bobbins. Mr. Varley did not confine himself to Faraday's discovery as to the electric current in the bobbins, but he talked about magnetism in the bobbins, instead of in the magnets. It was most important for the Court to consider that this invention of Varley's described a particular machine for carrying out a principle which had nothing whatever to do with compound winding, and referred back to a machine in which the development of magnetism in the magnets was caused in a totally different way from that which Brush had patented. Mr. Jameson proceeded to criticise in detail the different clauses of Mr. Varley's specification, directing particular attention to the clause "part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light. There are several well-known ways of doing this, but the method I prefer is to wrap the soft iron magnets with two

Digitized by Google

insulated wires, one having a larger resistance than the other—the circuit of larger resistance is always closed and the circuit of less resistance is used for the electric light." Mr. Jameson said it might be that with their present state of knowledge Varley had described a series shunt; but the question was whether Varley understood what he was talking about. and was it described in such a way that any person could understand it. Varley went on to describe a machine, and when they came to the end of his claims they found that there was no claim whatever made for this so-called invention.

LORD McLAREN: He did not claim compound winding; but perhaps he did not claim it not because he did not understand it, but because he did not think it was new.

Mr. JAMESON replied that Varley made the excuse that he thought it had been anticipated by the invention described by his brother, between whom and himself feelings were very hostile. This brother, Cromwell Varley, read a Paper to the Royal Society, in which he described wire or sheet copper put round the magnets so as to preserve a certain amount of residual magnetism; but to close the reference to Varley's specification Mr. Jameson drew their lordships' attention to the diagrams, and stated that they would look in vain for any indications of a series-shunt winding machine. Mr. Jameson then went on to quote at considerable length from the evidence of Prof. Silvanus P. Thompson as to the electrical absurdity of Mr. Varley's suggestions. He next quoted at great length from Sir William Thomson's evidence, to the effect that if anybody followed the directions in Varley's specification he would produce an unworkable machine. When they came in the middle of this specification to the lines regarding the winding, that might now be held to describe compound winding. They were not inconsistent with it, except as to the first two lines. Reading that now, it would be easy for any person to get rid of these two lines, and say they were a mistake. But going back to the state of knowledge at the time the machine was made, in Sir William Thomson's opinion it would put any person off the scent. And although a person might be led to it as in one passage, it was not such a description as to amount to an anticipation of Brush's patent. It was very important with regard to the state of Varley's own mind to consider this matter, because he had no conception of what he was doing himself. That was shown by Varley's own evidence, because he did not claim this great improvement, as he considered he was anticipating. But Sir William Thomson and the other skilled witnesses said Varley's specification had nothing whatever to do with series-shunt winding. Mr. Preece and Prof. Perry and Mr. Brush had all given evidence of a very decided nature. Mr. Brush's machine had remained in use until the present day, with hardly any modification of its original construction. Now, the next thing he asked attention to was the history of Varley's machine, and the mention of prior use. He contended that it was not proved that this machine was a compound-wound machine. There were two wires certainly upon the magnets, but they were arranged in such a way that they might be coupled up in a great variety of manners owing to the number of terminals they had in the machine. Accordingly, as they were coupled up in one way or another, they might either have series-shunt machines or a shunt machine, or perhaps a machine excited separately. Whether that were so or not he (Mr. Jameson) submitted there was no public user in the proper sense of the word, as this was properly an experimental machine; and that although numbers of the public witnessed the experiments, they came to nothing more. He therefore appealed to the law that merely experimental machines, never brought into regular use and thrown aside altogether, would not be permitted to invalidate a subsequent patent of a useful invention.

The LORD PRESIDENT: If the other side is right in holding that Varley's disclosure was an anticipation of your invention, it does not matter whether it was used afterwards or not.

Mr. JAMESON: That is so.

The LORD PRESIDENT: But, on the other hand, if it is not a disclosure of something equivalent to your invention, although it is used, that will not interfere with your invention. What bearing has this upon the present case?

Speaking with regard to Cromwell Varley's communication, Mr. JAMESON said that Varley was put into the witness-box and cross-examined as to why he did not claim this as an invention. His reply was that he did not claim it because of the communication of his brother Cromwell, with whom he was on very bad terms. That was very important, because it showed that he did not know that it was compound winding; or it showed that at best he had an exceedingly hazy notion of what he was thinking of. Now, if he had no clear conception of what he was recommending, and no clear conception of the effect of it, he would be very unlikely indeed to describe it in clear enough language to allow other people to understand it. Putting the case in the strongest view for the other side, what he said was, that all Varley had was a very hazy and indistinct notion of winding the magnet with two wires, and that he had no clear conception of how these would act, and how the machine was to be coupled up. Even assuming this specification is intended to disclose series-shunt winding, and that this machine is made in conformity with that specification, it is quite possible that my friend would not be able to succeed upon the point of the user of his machine. For instance, if you turn to the evidence of Gorman and others, who were connected with the firm of Siebe, Gorman and Co., at whose works Varley's machine lay for some time, their evidence showed that on all occasions upon which the machine was brought out it was for the purpose of seeing what mechanical requirements were necessary to make that machine go well. After trying it again and again it was put aside, and the result was that Mr. Varley became convinced it was an unworkable machine. Instead of making it public or doing anything more about it he sent it away to this gun metal store of Siebe and Gorman's, and allowed the machine to remain there from 1877 until 1887, when it was brought out for the purposes of the case against Mr. Brush. That was the history of the machine. As to the machine itself, Sir William Thomson and Professor Perry both said it was plainly an experimental machine, on account of the quantity of terminals. Then Mr. Preece said that Mr. Varley made a series machine in 1866 and exhibited it at the Inventions Exhibition of 1885. Mr. Varley was awarded a gold medal for it, but nothing was said about the wonderful discovery of series shunt he alleged he had made in 1876, nor of the machine which was constructed on that principle. Mr. Jameson contended that he had shown very clearly not only what sort of machine this was, but also what even the inventor thought of it. Mr. Varley did not bring it forward at all at this Exhibition of Inventions, and nothing was heard about it until it was brought out in the Crompton case. Varley himself was asked about this, and he gave some excuse about pecuniary affairs. He said he was carrying on experiments with the machine, and also making fresh machines to carry out their experiments. Even by his own confession, Varley had begun then with experiments. He would shortly point out to their lordships the history of the Brush machine. In point of fact, it had been largely used at home and abroad. Mr. Imray himself, a witness for the pursuers, admitted very candidly that the series-shunt contained the constant potential, and, at all events, the self-regulation. Mr. Brush brought in this self-regulation to an extent never before approached. It had come to be worth a great deal since the introduction of the incandescent light. The result had been that this machine of Mr. Brush's had been published, and it was taken up by a company, and the machines had been sold both in this country and America since 1878, when this patent was taken out. That was all he need say upon the evidence in the case, and the next matter was the question of law applicable to the evidence. As to the law, he had to say generally that whatever was essential to the invention must be read out of the prior publication. The question was whether this patent of Varley's disclosed such specific details of compound winding as to amount to prior publication of this discovery patented by Brush. Brush set forth his object, but there was no object set forth by Varley. Varley's object was apparently the extraordinary one of storing up electricity in the bobbins; and the details led to confusion. Varley went on to suggest certain ways of winding the magnets, but he gave no specific directions that would enable a person to carry that knowledge into useful effect. Then they had the most learned electricians in the world telling them that the specification was full of misleading information. The result was that no outside person could reckon with confidence on attending to Varley's specification, not even the inventor himself. But Mr. Brush came afterwards and showed the means by which the end could be attained; and, according to the law as laid down by Lord Chelmsford, he was entitled to the invention, as his machine had been used since with invariable success. On the whole matter of law Mr. Jameson submitted that the Brush Company were entitled to a verdict in their favour on the ground that Varley's specification was not an anticipation by prior publication of the invention which was set forth in Haddan's or Brush's specification and letters patent. The next question, whether there was anticipation by prior user of the machine, must stand by itself apart from the specification altogether. Now, he thought it was quite settled law that anticipation by a similar but useless machine would not invalidate a patent. A subsequent patentee who invented a useful machine and gave the world the benefit of it, was not to have his rights taken away from him by some person coming forward who had invented a useless machine some years before, and was not able to make anything of it. Nor, again, would an experimental machine that had been set aside after trial invalidate a subsequent patent. It did not require that the machine should have been in use down to the time of the patent being brought forward. It would do if it had been regularly used and put to useful work, even if that use had been discontinued; but it must have been used in some way different from mere experiments. Varley never made a machine in which compound winding was practical; there was no user of it. He therefore submitted that Mr. Varley's machine was unworkable, and that there was no good ground for reduction of this patent of Mr. Brush's, which had been found so successful.

Mr. GRAHAM MURRAY, for the pursuers, said he would begin with the commutator, upon which the Lord Ordinary was in his favour, and consider the alleged discrepancies between the provisional and the complete specifications. He did not think there was any difference between them as to the law of the matter. He thought they were clearly at one that what must be disclosed in the provisional specification was the general nature of the invention, and what must be disclosed in the further specification was necessarily a sufficient way of carrying that out. But if he were able to show that the thing disclosed in the complete specification was a different invention from that in the provisional then the patent was bad. With regard to the commutator their lordships would also see that the divergence between the provisional specification and the final specification came to this, that all that was discovered, all that was claimed in the provisional specification, were mere mechanical improvements having to do with the circumstances of the commutator. They should take the commutator as a known thing, and they were giving a new mechanical construction to the commutator so that it would wear better. But when Haddan came to the final specification he had discovered something else, and that something else he claimed, and thereby the electrical efficiency of the machine was enhanced. In the original specification a disclosure was made of what might be called a mechanical construction of the commutator, and that alone, but in the final specification they claimed the insulating segments T, which were for the purpose of cutting armature bobbins out of circuit when they were crossing the neutral points. That was foreshadowing an invention that was not in any way disclosed in the provisional specification. Mr. Jameson had said that Mr. Brush had not claimed that this was a useful function, and that by the segments T they only claimed a mechanical arrangement of the commutator. That was not what Mr. Brush said. Mr. Murray then proceeded to point out the view that Mr. Brush him-

Digitized by Google

self took of the matter. The only question, he said, which remained was whether there was any indication at all of this in the provisional specification. That there was a novelty in this cutting out of the armatures, if they excepted Varley, there was no doubt. No witness when he was asked to point out anywhere in the provisional specification a single passage or line that disclosed an invention by which this electrical result of cutting out the armature at a neutral point of the circuit was obtained could do so. The argument on the other side was not rested on the slightest attempt to show that the province of the insulating segment T was disclosed in the provisional specification. It was rather directed to try to prove that in the complete specification and claim Mr. Brush did not imply any such thing. But the person who must best know about it after all was Mr. Brush ; but Mr. Brush did not see the danger of giving evidence about this long before the proof that was taken in the Court of Session and before objection could be urged. At the same time it was clear that if it had not been for a defect in the original specification they should not have had the argument against it. Therefore upon this point he submitted that when the patent was looked at, and especially when the provisional specification was looked at, it was impossible not to see there was a meritorious invention in the complete specification and in the claim that was never adumbrated at all in the original specification.

The Court adjourned till next day.

FRIDAY, May 30th.

Mr. GRAHAM MURRAY, continuing his speech, said he should now like to say a few words upon the claim itself, and to show that it was impossible for his friends on the other side to urge that that claim was not for an electrical contrivance for having an insulating segment T. It was quite impossible for them to say that there was nothing but a claim for a mere mechanical contrivance. Therefore they tried to avoid it by enlarging the provisional and by lessening the final specification. Now claim 4 was for "a commutator having metallic insulating segments T, substantially as shown in division 3." That claim was nonsense, unless it was a claim for a segment T in its character of an insulating segment.

The LORD PRESIDENT : You say the point in which it exceeds the provisional specification is the insulating segments T ?

Mr. MURRAY : Yes, the whole stress being upon the "insulating." It was a curious thing to disclose that electrical advantage and have a claim appropriate to it, and afterwards to say that they did not mean to claim it. There were two answers to the reclaimers' view upon that point—first, that claim 4 would be useless, because they had already got it ; and, secondly, that suppose claim 4 were read as not a claim of an electrical advantage at all, but a claim merely of a mechanical arrangement, then it was not patentable, because the only patent would be making the insulating segment, which had been of wood, metallic. Therefore, he thought, he put his friends on the other side in a dilemma on that point. Another point he made here was that the other side always read "insulating" as if it were "insulated ;" but it was the power of insulating that was described and claimed, not something insulated. That was all he had to say on the discrepancy between the provisional and final specification ; but there remained the question whether Brush's commutator, as described in that specification, was not invalidated by prior use. Now, there were what were known as the Manchester, or Wilde's commutators. Evidence with regard to them he need not read, for this very good reason, that he did not think the other side contended that he had not perfectly well proved that these commutators were used. Their point, and the Lord Ordinary's point, was that these commutators were not proper anticipations. He then showed two of the Manchester commutators, one with and the other without wearing segments. These commutators were taken off the shaft, and the shaft itself was insulated from one-half of the commutator, and made to be in electrical connection with the other. That was to say, instead of having a pair of wires, as in Brush's commutator, the metallic shaft of the machine itself served the electrical purpose of one wire, and one wire only was brought into electrical connection with the other half of the commutator. That was the difference upon which the Lord Ordinary had gone. The Lord Ordinary said in his note that with regard to Varley's and the Manchester commutators, he thought it might be said "that they are cylindrical with metallic sub-segments, having metallic wearing segments, detachably attached. They also had an 'insulating body,' or substance. Yet with all these points of similarity I do not regard them as anticipations of the defenders' commutator. The insulating hub, or body, of the defenders' commutator is the 'body,' or basis on which his commutator is constructed, to which the various parts of this commutator are attached. This cannot be said of the Varley, or Manchester commutator, in which the insulating substance does not form the body or basis of the commutator at all, and insulates not the whole commutator, but only one section of it." Now, his lordship had made a slip there as regarded Varley's commutator. Varley's commutator was exactly like Brush's in the question of what parts were insulated, and what were not ; but with regard to the Manchester commutator, the Lord Ordinary was right. In answer to the Lord Ordinary, he had to quote the testimony of the witness Prof. Silvanus Thompson, who, speaking of the Manchester commutator, said :—"The use of the shaft in the machine as an electrical connection is a mere mechanical equivalent for a wire. It has been so used for a long time." Of course, if Prof. Thompson was right in that, then the converse of that was equally true—that the wire was a mere mechanical equivalent for the shaft. Therefore, that so-called electrical difference was really no electrical difference at all. It would not enable the other side to support a new patent if he had already discovered and used a commutator which had all the other parts exactly the same as Brush's ; simply because, finding a commutator which used the shaft as one of the means of electrical connection with the armature, and a wire as the other means, they substituted, therefore, two wires, and discarded the shaft altogether, the shaft being, of course, a very thick wire. He should like to put the matter in another way, which put the other side in a dilemma. If they were so particular as to deny that so far as that commutator was concerned there was any electrical discovery whatever, when he came to examine the Manchester commutator they must not say :—"True it is that your commutator is mechanically the same device, but electrically considered it works in rather a different way," because the communication was through the shaft instead of through a wire. Therefore, he submitted on all these grounds, Wild's commutator was an anticipation of Brush's. The Lord Ordinary made a slip with regard to Varley's commutator, he meant the commutator as made on Varley's machine. During the proof they got leave to take off some of it, and they could see the place where it was prised off. He showed to the Bench bits that had been taken off. The brass was "the sub-segment placed in electrical connection ;" the iron was "the wearing segment, detachably attached ;" and they could see the character of the little screw by which it was attached to the sub-segments His friends on the other side made this point that it could not be detachably attached when it required a hammer and chisel to take it off. It was true that it was taken off with a hammer and chisel under the inspection of Dr. Hopkinson ; but it must be remembered that nobody knew anything about that machine. It had lain in Siebe and Gorman's, and was covered with rust ; and, of course, they had taken off the commutator with a cold chisel and a hammer. The Court, however, would have no difficulty in coming to the conclusion that if it had been known that it was fixed in the way it was, there would have been no reason for hammering at all. All they needed to do was to cut a little nick in the head of the screw, put in a screwdriver and out with it. The only difference between the two was that while in Brush's the screw head was allowed to remain on, in Varley's the screw head was cut off, and the top of the portion left was hammered into a sort of a rivet. That finished what he had to say about the commutators. Practically it came to three points—disconformity between the provisional and the final specification, anticipation by Wilde's commutator by public use, and anticipation by Varley's commutator by public use. He now passed to the more general and interesting part of the case—the question of compound winding. There were two points upon that—publication by Varley and prior user in respect of Varley's machine. The real truth was that that invention was made for one purpose, and which, by an extraordinary piece of good fortune, was available afterwards for another purpose of infinitely greater importance. Whether Varley or Brush invented compound winding it was clear to demonstration that neither Varley nor Brush saw the real merit or real importance of the invention which they made ; and the great commercial value of the invention was due to something else entirely, which neither Varley nor Brush at that time knew anything about, and which was not discovered for some years afterwards. Until the great discovery of the incandescent lamp there was no use for a dynamo that would maintain constant potential ; but after constant potential became a necessity. It was provable to demonstration that constant potentiality was no part of Brush's purview at the time that he entered into that patent. Nay, more, it was proved that constant potentiality did not depend upon compound winding ; and although compound winding was a very convenient basis from which to start upon their search for constant potentiality, the true discovery of constant potentiality depended not upon compound winding, but upon certain other conditions altogether, which might really be got in a pure shunt-machine, just as much as in a compound-wound machine, and which if got in a compound-wound machine, depended not upon the fact that it was a compound-wound machine, but upon the proportion of resistance between the thickness of the two wires. What Brush really wanted was to secure a machine that would always have a permanent field ; in other words, that would maintain the passage of the electric current through the bath in the proper direction. Brush said, "other useful applications of a permanent field will readily suggest themselves ;" and it was upon these words that his friends upon the other side had now to hang constant potentiality. But there Mr. Brush himself forsook them ; for in his evidence in explaining the words "permanent field," he said they did not mean unvarying field, but a permanent field of unvarying polarity ; and again, "a field of constant polarity, and one not liable to reversal under normal conditions." But that matter did not rest there. He was glad and willing to take the other side's own witnesses, and no others, in support of his view. Prof. Silvanus Thompson said : "*Q.* Do you take it that the object of Brush's invention is to give a constant potential ? *A.* He never says so." Again, he said that "he thought that the success as to constant potential depended rather upon the conditions of the individual machine than upon the question whether it was series-shunt wound or shunt-wound ;" and again, that "he should have expected much more specific instructions than were given in Brush's specification if the patent had been one for constant potential." Further on he gives a piece of very cogent evidence to the effect that as soon as a suitable incandescent lamp was discovered, it became desirable to have constant potential, that a great many methods were tried, and that most of the devices were prior to the discovery of those conditions of proportionate resistance, and so on, which they now knew, and which ensured constant potential in a series-shunt machine. He called that most cogent evidence, because it showed that there was Brush with that very machine, compound wound if they liked, at the date when, a suitable incandescent lamp having been found, constant potentiality was desirable, and yet it did not occur to him or any one to solve the question of constant potentiality by means of compound winding ; because they tried some other plans. It was not until some one discovered "those conditions of proportionate resistance" that they were enabled to turn a simple series-shunt machine into one that would ensure constant potential. That was a most eloquent commentary upon any attempt to show that Brush had reached constant potential at the time he took out his patent. He thought he had shown that as regarded constant potential, the real merit of the invention was neither known to Brush nor to Varley. He now came to Varley's

Digitized by Google

patent; and there the question was whether Varley did or did not disclose compound winding. His friends on the other side had tried to read, or rather to misread, Varley's specification by the light of another specification of Varley's, in 1867. He did not think that was legitimate in the construction of Varley's specification in 1876. Varley was the first inventor of a self-exciting dynamo, and it was that machine of 1867 that got a prize at the Electrical Exhibition. All reference to that machine ought to be kept out of this case. Coming, then, to Varley's specification of 1876, they found that Varley gave a description of his machine; and it would be convenient if their Lordships would follow the description of the models upon the Bench, because the cross-examination of the defenders' witnesses followed that line. Mr. Jameson had read the examination in chief of these witnesses, all of whom said the specification was misleading. He claimed to say that not one of them stuck to that position in cross-examination. They were forced to admit that the words there used were consistent, and consistent alone, with compound winding. Their Lordships, however, would, after all, probably be more inclined to take their own view upon that, than that of any of the witnesses; and, therefore, he asked their Lordships to follow with him upon the model the precise phraseology, and see how inapplicable the language was to any other way than compound winding. Mr. Murray then by aid of the models described the three methods of winding—series, shunt, and series-shunt; and proceeded to say that Varley described his method of winding thus:—"Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets." He paused there to say that that was evidently appropriate to describe either shunt proper or the shunt portion of a series-shunt machine, because in both it was true that part of the electricity was diverted to maintain the magnetism of the magnets. "And the remaining portion is used to produce the electric light." Now, said his friends on the opposite side, "You must read in these words 'is only used to produce the electric light,' because, as a matter of fact, in a compound-wound machine, the remaining portion of the electricity is used not only to produce the electric light, but also to maintain the magnetism of the magnets." Leaving that over in the meantime, he went on, "There are several well-known ways of doing this, but the method I prefer is to wrap the soft iron magnets with two insulating wires, one having a larger resistance than the other." He paused there again, for here was the bottom of the fallacy upon which the defenders' witnesses proceeded. There were two ways in which the sentence grammatically could be read. One was:—"There were several well-known ways of doing this, but the one well-known way I prefer is so and so." All his friends' witnesses started by reading it in that way, and they said triumphantly that the only well-known ways were ways that did not include compound winding. But the other way in which the sentence could be read, and his way of reading it, was:—"There are several well-known ways of doing this, but I show unto you a more excellent way, which is wrapping the two magnets with two wires." Grammatically speaking, he was free to admit there was nothing to choose between the two, the use of the disjunctive "but" being equally appropriate.

The LORD PRESIDENT: There is a change in the word "way." He uses "method."

Mr. MURRAY said that was in his favour. He did not think any one had seen that hitherto, and he thanked his lordship for pointing it out. What was Varley's method? He wrapped the soft iron magnets with two insulating wires, one having a larger resistance than the other. It seemed to him perfectly clear that that sentence put out of the way either pure series or pure shunt; and for this reason—why have two wires when you only need one? They did not need to wrap the two magnets with two wires unless they were going to pass a current through them. There was a wild attempt on the part of Mr. Preece to represent that that might be done for the induction purposes, but he had to discard the attempt. But then came a very important sentence, "The circuit of larger resistance is always closed, and the circuit of less resistance is used for the electric light." That was perfectly appropriate to series-shunt. His friends on the other side wanted to read in the word "only." That necessitated them to say that that was pure shunt, because the circuit of less resistance was used, not only for the electric light, but also for the magnets. But then the next sentence drove them from their position:—"When the electric light is being produced, the greater portion of the electricity passes through the circuit of less resistance, which I term the electric light circuit, maintaining the magnetism of the magnets and producing the light." That clinched the whole concern, because it just left out the word "only," which his learned friend wanted read in. It would not be true, and could not be true of a shunt arrangement, because in a pure shunt arrangement the circuit of less resistance is maintaining the magnetism of the magnets, and therefore they could not read that sentence as consistent with any method of arrangement except compound winding. "When the electric circuit is open from any cause, the electricity developed passes through the circuit of greater resistance only," that was to say, the shunt, "and maintains the magnetism of the magnets." How very clear all that became if they substituted the word "shunt" for "the circuit of greater resistance." Having read the specification in that way, he said that nothing could be clearer or plainer than that, and he never saw in his life a more absolutely unscientific spectacle than the defenders' witnesses presented in deliberately sitting down and determining not to understand the thing, in order to avoid the one conclusion to which in the end they were forced, namely, that that was series-shunt winding, and nothing else.

LORD McLAREN: I suppose we must take it that the self-excitation of the magnets by the machine was known at the date of this specification, although not widely known?

Mr. MURRAY: Yes.

LORD McLAREN: The only question between you is whether this passage, which undoubtedly describes one form of compound winding, describes compound winding in which the wires that go round the magnets receive their electricity from a separate source or from the same source. There is no direct indication of a separate source.

Mr. MURRAY said he should be able to read evidence that would utterly drive separate excitation out of the question. He wanted first of all to show that the defenders' witnesses were really forced in the end to admit that his was the only clear construction. His point upon Varley's description was this, that if the blindest workman in the world did what Varley told him he would have compound winding in spite of himself.

LORD McLAREN: What is the criterion you propose to apply to the interpretation of the specification? Must it be so clear that a workman of ordinary skill would understand it, or would this be sufficient that this particular part of the specification would enable a person already familiar with dynamo machines as known at that time to add compound winding to the other requisites?

Mr. MURRAY: I do not think honestly that there will be much between us in the law. I am quite willing to take it as already laid down by the Bench. But it is difficult to make an exact definition of these sort of things. Certainly an anticipation necessarily is an anticipation which fairly discloses the invention, and discloses it in a way that is understandable by a person well versed in the science.

LORD McLAREN: A person who knew dynamo machines as then existing.

Mr. MURRAY: Certainly, and a person of great intelligence. But while that was so, he submitted that a very stupid person would have understood that specification of Varley. Proceeding to deal with the evidence, he said he wished to take the defenders' witnesses, and to show how, in cross-examination, they had been dislodged from their position. They all commenced by saying that Varley's description meant series, or shunt, or separate excitation; but he had made them confess that the words were inconsistent with shunt, with series, or with separate excitation, and that there was nothing left but series-shunt. Mr. Murray then read from the evidence of the defenders' witnesses, Profs. Silvanus Thompson and J. Perry, Sir William Thomson, and Mr. Preece, to prove what he had just said. Mr. Preece had, he said, gone into the box very confidently, holding the view that the whole thing was inconsistent with series-shunt; but when he was pressed he admitted that it was not so. He was pushed from one corner into another, and then when he was floundering—if the term might be used without rudeness—he seized upon the idea of double shunt only to abandon it. He need scarcely say that as regarded the pursuers' witnesses their evidence was clear and distinct in the view that it was compound winding, and their testimony was unshaken in cross-examination. Mr. Murray next referred to some matters of criticism that here and there had crept up in the defenders' case. Those with which he would deal were the use of the word "divert," the use of the word "circuit," and the question of "bifurcation." With regard to the word "circuit" the witnesses said that the term accurately used meant circuit from end to end, and that no one ought to speak of "series circuit" or "shunt circuit," that being technically incorrect. That might be, but nevertheless Brush himself, and several of the witnesses themselves, fell into these very inaccuracies. With regard to "bifurcation," it had been suggested by some of the witnesses that bifurcation was necessary, as of course it was, in that arrangement, and that nothing was actually said about bifurcation in Varley's patent. Sir William Thomson disposed of that perfectly satisfactorily; for he said, in his evidence, that birfurcation of an electric current by splitting a wire was not beyond an electrical workman, and that if he found it necessary for any reason to bifurcate his current, splitting the wire would readily suggest itself. Coming to the question of whether separate excitation was part of Varley's patent, he said he would explain the part of the patent which enabled him to put out of the way separate excitation altogether. There were certainly two plans which helped them to do that, and one of them was exceedingly strong and utterly inconsistent with separate excitation. He quoted from Varley's specification as follows:—"The number of bobbins in each group may be two or four or eight; the number of commutators employed may correspond to the number of bobbins forming the group, or they may be increased in number; and when electricity of a very high potential is desired, the commutators may be increased to the same number as the bobbins." Then, at another part, Varley said: "When the number of commutators correspond to the number of bobbins forming a group, the ends of the insulated wires of each group are joined side by side to the respective discs of the commutators." Varley went on to say: "The springs which rest against the commutators are so connected as to form a continuous electrical circuit from one to the other, through the metal discs of the commutators." Their Lordships would see that that was absolutely destructive of the idea of separate excitation from a separate portion of the armature, because, if they had separate excitation from a separate portion of the armature, they must have that separate portion commuted by a separate commutator of its own, and of course taken away to the magnets; whereas the rest of the electricity developed by the armatures would be commuted by its commutator and taken away to the circuit. If they put these two commutators in direct electrical connection, they destroyed the whole thing. Therefore, inasmuch as there was only one method of winding given, the patentee was of course entitled to wind any machine which had been previously described by that method of winding, and he proceeded to compound wind a machine which had a commutator of such a construction that separate excitation was impossible. In support of that contention, he quoted the evidence of Sir Wm. Thomson Profs. Perry and Silvanus Thompson, and Mr. Preece, the defenders' witnesses, and Mr. Swinburne and Prof. Ewing, the pursuers' witnesses. Dealing with what counsel on the other side had called "electrical absurdities" in Varley's patent, Mr. Murray said Sir Wm. Thomson said that Varley had a wrong theoretical idea, which resulted, after one of the armature bobbins was cut out of a certain portion of the revolution, in throwing in the bobbin again too soon. That was exceedingly temperately put; but one of the great peculiarities of electrical science was this, that although these gentlemen had discovered a great deal in one way, they had discovered uncommonly little in another. In fact, electrical

Digitized by Google

science, in one sense, was still entirely an empirical science. Assuming that Varley was wrong when he went a little beyond his province and described in his patent the way in which electricity was formed and magnetism was stored, it did not make any difference in his machine, except what Sir William Thomson said about leading to the bobbin being thrown in too soon.

The LORD PRESIDENT: We are not trying the validity of Varley's patent, but only what it disclosed.

Mr. MURRAY: Certainly. But there was another matter to which he would ask their Lordships' attention, and that was what Prof. Silvanus Thompson said, that "Varley's machine, such as it is, works or does not work quite irrespective of the theory on which it is constructed. The machine described in the specification is a workable dynamo machine, and at its date I do not know that there were any better." The machine which defenders' counsel wished to make out as a failure was described by their leading witness as one which at its date had no rival. Of course, the machine was a failure if they pitted it against the machines of the present time; but at its date it was a good machine, and in this question of anticipation it could not be described as a failure. But passing from that, there was a very good reason why Varley should have been anxious to introduce that compound winding. He had already admitted, as part of his argument, that Varley did not know that he was laying the foundation of constant potential; but he did know that part of his patent was concerned with a lamp, and the lamp which Varley constructed was a lamp for the proper working of which it was almost necessary that he should hit upon compound winding. The learned counsel described the lamp which Varley's machine was made to work, and gave reasons to show that it could not have been worked either by pure series or by pure shunt; but that the difficulties experienced by either of these methods were avoided with series-shunt. In support of his view he quoted the evidence of Mr. Swinburne, and Profs. Ewing and Silvanus Thompson. He would pass to another branch of the case, which his friend Mr. Jameson did not touch upon, but which he submitted could not be treated so cavalierly. He referred to the fact of that compound winding having been reached through Varley's specification by no less than four mechanics. The models made by these apprentices from Varley's specification varied in form, but they were all equally compound wound. He did not say that it was conclusive, but it went a long way to show that the description in Varley's patent was not the terribly difficult thing to understand which some of the witnesses on the other side said it was. He proceeded to deal with the question of disclosure by prior use by the machine made under Varley's directions by Siebe and Gorman. That machine showed that it had got two windings round the magnets, and his friend could not deny that it could be perfectly easily used as a series-shunt machine.

LORD McLAREN: Have you evidence that it was in fact used as a series-shunt machine coupled up in that way?

Mr. MURRAY: I have got very good evidence of two sorts. It was used publicly to illustrate certain operations in a diving tank, and for the purpose of photographing an ice machine. They were not experiments on the machine itself. He quoted the authority of several cases with regard to what public use really was.

LORD McLAREN: Your point is that it is enough if the results are shown to the public, although no one can see how the thing is done.

Mr. MURRAY: Exactly so. If you put a book in a bookseller's window, that undoubtedly is good publication in the sense of the law. He went on to say that there was very good evidence to show how that machine was connected, in the sketch made by Varley in an old note-book. Sir William Thomson, looking at Varley's sketch, said it was series-shunt. The date of the sketch was about the date of the specification. There was another piece of evidence which showed quite distinctly that the machine was coupled up in series-shunt. A common workman who did not know anything about these matters, and could not explain the operation of compound winding, and therefore could not have been coached, gave evidence which showed how the machine was used. He quoted from the testimony of Edward F. Myers to show that certain results which he had noticed when Varley's machine was in operation could have been produced only by a machine coupled up in series-shunt.

LORD McLAREN: I think one can hardly doubt that that machine of Varley's was compound wound, although one cannot say whether it was a good one.

Mr. MURRAY: That is so; but it does not much matter; and the question of its being conceivably double-shunt, as Mr. Preece at one time said, is put out of the way, because if it was double-shunt the lamp must necessarily have had a key, and there was a joint minute put in stating that there was no key ever used with that lamp. He concluded by submitting that the Brush patent was bad, upon the various grounds which he had adduced.

At the close of Mr. Murray's speech, the further hearing of the case was adjourned till Tuesday.

TUESDAY, June 3rd.

The DEAN OF FACULTY (Mr. J. B. Balfour, Q.C., M.P.) addressed the Court on behalf of the defenders and reclaimers (the Anglo-American Brush Company). Dealing in the first place with the mechanism of the commutators, he addressed himself to the alleged disconformity between Haldan's final specification and the provisional specification, and argued that the Lord Ordinary, in giving judgment in the Outer House, had lost sight of the respective functions of a provisional and a final specification. His (counsel's) contention was, that the purpose of a provisional specification was merely to mention or disclose the nature of the invention. It was in the later and final specification that the particular details and the mode of carrying out the specification were given. The object of a provisional specification was to enable a man when he had got hold of a novel and useful idea to work it out during the six months' protection afforded to him. The Dean next proceeded to point out that Brush claimed a peculiar form of commutator, which combined cylindricity, durability, and repairability; and it was evident that the insulating segment T was within the general description and purview and aim of the provisional specification. The Lord Ordinary was with him (the Dean) upon the next question, namely, whether Wilde's or Varley's commutator was an anticipation of Brush's. No doubt in Wilde's commutator the shaft was used as an electrical equivalent for a wire; but Brush's commutator claim was for a combination, and while in Wilde's the shaft was an electrical equivalent for a wire, it was only for one wire, and could only work with an armature with one bobbin, in Brush's they could have as many rings of segments as they liked, and adapt it to the superior work that had now to be done. Another difference was that while in Brush's they had an insulating hub, in Wilde's, with the shaft doing electrical work, they would have considerable leakage of electricity, seeing that the shaft was in connection with the iron framework of the machine. Therefore, Brush was superior to Wilde in that respect. Then again, comparing Brush's with Varley's commutator, while in the former the wearing segments were detachably attached by means of a screw, in the latter they had to be broken off with a cold chisel or crowbar, with the result that the machine was damaged. Further, comparing Brush's method of attachment—a screw, with Varley's—a nail or rivet, the advantage was all on the side of Brush. No doubt, Varley's came very near Brush's with regard to the mechanism combination; but it did not satisfy either the description in Brush's specification, or the advantages claimed for it. He now passed to the question of compound winding. Mr. Murray had said that neither Varley nor Brush knew of the advantages, or the material advantages of compound winding at the date of their patents. Mr. Murray could not dispute that there was in Brush's publication a full, complete, and clear disclosure of compound winding, nor could he dispute that, until Brush made that invention in 1878, compound-wound dynamos were never even used or in the market. Now there were thousands of them; and whether or not Brush was anticipated by Varley, it was Brush and not Varley who had made that mechanism useful to mankind. While Brush's machine had become a world-wide success, Varley's—which was an experimental machine—was stowed away among rubbish in Siebe and Gorman's, and was never heard of, until it was resuscitated for the purposes of the Crompton case. While it might be true that Varley did not appreciate the value of his invention, it was not true of Brush, because Brush in his specification showed by his description that he appreciated what he invented. Mr. Murray's point was that there was no incandescent lighting at that time. No doubt there was very little; and while Brush might not have seen what fine measures of adjustment might ultimately be required to secure constant potential, he certainly devised and executed a mechanism which necessarily could not help making a very near approach to constant potential, and which did make as great an approach to constant potential as appeared to have been necessary at that time for electro-plating. Comparing the obscurity of Varley's specification with the clearness of Brush's, the Dean said that the reason why Brush succeeded was that he drew up a proper specification and went into the market with his completed machine. They got some light on the matter from Varley's own evidence. There was no doubt he was a man of great ingenuity, but without the staying power to work his ideas into practical form. While he seemed to have visionary or floating ideas they could not be practically put together. Varley seemed to have launched this general description, and then proceeded to see whether it would work. Although there might be dangers attached to experiment, they were certainly not those dangers of first adumbrating something in writing and then trying if it would work. The trial in this case proved that it would not work; and although 14 years had elapsed since then, no machine, except that which was taken from Siebe and Gorman's yard, was ever made, and no machine ever succeeded. The Dean then proceeded to contend that it was not enough to take a few lines of a patent and say that because they were not inconsistent with compound winding, then compound winding was disclosed. Before a thing could be a disclosure of a machine, it must direct a man how so to make it that he would be certain of the result. He was not merely to get a description of a thing consistent with one thing which might be consistent with a dozen other things. He must get a description which marked out one machine from all others. While there were some lines in the specification which might be extracted out of this description which would be consistent with compound winding, yet he disputed that consistent and description were synonymous terms. Then, again, a great peculiarity of this case was, that if Varley should prove to be the inventor, after having got an enormously valuable invention, he did not claim it. Varley stated, with regard to the winding of the magnets, there were several well-known ways of doing this, but the method he preferred was to wrap the soft iron magnets with two insulating wires, one having a larger resistance than the other. The circuit of larger resistance was always closed, and the circuit of less resistance was used for the electric light. It was said that here they came nearer to compound winding. It was said that the previous two lines he had referred to described compound winding; and now Varley proceeded to say that there were well-known ways of doing this, that there were well-known ways of compound winding at a time when it had never been known. If an ordinary workman of that time had been started on this wild-goose chase by being told to separate the total electricity into two parts, and then was informed that there were several well-known ways of doing this, what would he do? He would look to his common knowledge to see where were the several well-known ways of doing this, and he would think of the ways which were all inconsistent with compound winding. Varley went on to describe something which he (the Dean) did not dispute might be consistent with compound winding. What he said as to the method he preferred, of wrapping soft-iron magnets with two insulating wires, one having a larger resistance than the other, up to a certain point was concerned with compound winding, because they had in compound winding

Digitized by Google

soft-iron magnets, wrapped with two insulating wires, and one had a larger resistance than the other. They had a shunt wire with a large resistance, and a series wire with a small resistance. But they were not told where those wires came from, and how they were coupled up. They might have come from the armature, and they might have come from the outside altogether. Varley told them that there were some well-known ways of doing it, but no human being had ever done it in this way before. Then it would not do to extract a line out of the specification at one place and another line out of another place, and a third line out of a third place, and putting them together say that meant compound winding. That did not constitute a clear and definite instruction, according to which a workman of the year 1876 would be able to construct the machine. The only other point he had to deal with was regarding the machine which was constructed in Siebe and Gorman's yard. The people there were skilled mechanicians, and they had every advantage; but yet they never got beyond the point of experiment.

At the conclusion of the Dean's speech the Court rose for the day.

WEDNESDAY, June 4th.

Mr. DICKSON replied for King, Brown, and Co. He said that with regard to compound winding, undoubtedly Varley, like Brush, was before his time in the discovery, and the reason why Varley had not followed out the patent of compound winding was, in the first place, because he had not funds, his partnership with Siebe and Gorman having broken up; and in the second place because he thought if he claimed compound winding he would endanger the patent he had, seeing he was apprehensive that his brother, Cromwell Varley, whom he thought had already found out compound winding, would interfere. Varley's scheme was distinctive enough; for, while its main purpose was to produce the electric light there were statements that it might be useful for other purposes. With regard to Varley's machine, he said that it had been publicly used in Siebe and Gorman's. It was worked there and people came to see it. It was worked to make experiments in a diving tank; and that was surely anticipation by prior use. Varley had in view compound winding when he had that machine constructed.

At the conclusion of Mr. Dickson's speech, the Court took the case to avizandum.

Crompton and Co. (Limited) v. the Elieson Electric Company (Limited).

In the Queen's Bench Division of the High Court of Justice, on Thursday, the case of Crompton and Co. (Limited) v. the Elieson Electric Company (Limited) came before Mr. Baron Huddleston and a special jury. This was an action brought by the plaintiffs, Messrs. R. E. Crompton and Co. and Messrs. Crompton and Co. (Limited) to recover £454 odd for goods sold and delivered and work done between May and November, 1888. The defendants admitted the plaintiffs' claim, subject to a reduction of £70. They, however, counterclaimed for damages laid at £10,000, for injury to their business and reputation, caused by the alleged negligence of the plaintiffs.

Mr. F. Moulton, Q.C., and Mr. Graham appeared for the plaintiffs; while Mr. Finlay, Q.C., and Mr. Bousfield represented the defendants.

The defendants having admitted the claim of the plaintiffs, subject to a deduction,

Mr. FINLAY opened the defendants' case in support of their counterclaim. He said the defendants had a large claim against the plaintiffs for the negligent way in which they conducted and superintended the working of certain electric engines. The defendant company was formed in June, 1887, for the purpose, *inter alia*, of providing traction by means of electricity, and it took over the business and the rights vested in a preceding Company known as the Electric Locomotive and Power Company, which had an arrangement with the North Metropolitan Tramways Company for supplying electric engines for the purpose of drawing tramcars over a part of the line from Stratford to Manor Park. These engines were used experimentally with the view of their being run over the entire section of the line between Manor Park and Stratford, and at other places. Under contracts existing in May, 1888, the North Metropolitan Tramways Company were paying the defendants large sums for the use of the electric engines, for the maintenance and repair of which the defendants had erected extensive works and buildings at Ilford, Essex. In July, 1887, there had been something wrong with the armatures of the motors, and the plaintiffs were called in to supply fresh armatures. This they did; and up to March, 1888, the system of locomotion with which the name of the defendant company was identified was perfectly successful. In March, 1888, the defendants were desirous of enlarging their operations and providing more engines, and undertaking the whole of the tramway service of the North Metropopolitan Company, and for that purpose larger works were constructed. The defendants proposed to utilise works at Plashet Hall, and Messrs. Crompton suggested that they should be entrusted with the construction and superintendence of these new works. On the 8th of May it was agreed that they should be responsible for the sole management of the works and the running of the engines on the line, the defendants giving them a weekly cheque for expenses and wages of the men. Everything the plaintiffs wanted was provided and paid for by the defendants. The superintendence of the plaintiffs continued from May until September, 1888, when there was a series of serious breakdowns. The Tramway Company had been running their cars by horses during the time the defendants were getting the engines ready; and on the 5th of September, at the plaintiffs' request, defendants wrote to the Tramway Company to the effect that the electric engines would be ready to resume running on the 18th of that month. On the 10th, 11th, and 12th of September serious accidents occurred. In the first place, the plaintiffs sent out engines insufficiently stored with electricity, and consequently the tramcars stopped short in busy streets, where the traffic was great. Secondly, they did not leave the points connecting the siding with the main line, and consequently the wheels of two of the engines were broken. Thirdly, through a mechanical defect, the rack of one engine was broken. The plaintiffs were solely responsible for these accidents; but the result to the defendants was that on September 13th the North Metropolitan Tramways Company ordered the running of the cars by electricity to be discontinued. Consequently the defendants lost the profits of their contract with the Tramway Company, their works at Ilford were rendered useless, and their reputation as providers of traction by electricity had been greatly damaged by the negligence of the plaintiffs.

Mr. THOMAS BRYCE GOWER, secretary of the Elieson Electric Company, went into the witness box and gave evidence, bearing out Mr. Finlay's statement, and was still under examination when the Court adjourned.

REPORT OF THE FRANKFORT ELECTRIC LIGHTING COMMITTEE.

The following is an abstract of an interesting Report of a Committee appointed last autumn by the Town Council of Frankfort-on-Main to deal with various matters in connection with the question of electric lighting. This Committee, which consisted of Profs. Galileo Ferraris, F. Uppenborn, H. F. Weber, Kittler, and Herr W. H. Lindley, reported on the subject of alternate-current motors, transformers, arc lamps, and meters, and discussed at great length the advantages and disadvantages of various systems of supply. The results of some experiments which were undertaken by this Committee to test the efficiency and capabilities of the Ganz alternate-current motor were published in *The Electrician* of March 7, 1890, p. 453.

Alternate and Direct-Current Arc Lights.—In order that the lighting effect of arc lights fed by the two systems might be tested, the Corporation built two exactly similar rooms, provided with windows on the north side only. In one room was a Schuckert direct-current lamp, and in the other a Ganz alternating-current arc lamp. Both lamps were placed at the same height and consumed equal amounts of energy. The five members of the Committee each observed, from outside, the illumination produced on the three sides, the ceilings, and the floors of the two rooms. In the result, it appeared that the illuminating effects of the alternating-current lamp and the direct-current lamp were as 1 : 1·23. For out-door illumination, all the observers agreed in putting down the illuminating power of the alternating-current as less than that of the direct-current, in the proportion of 4 to 5. It was proved that the alternate-current lamp required more amperes than the other; but it also appeared that if the total radiation was taken into account, and not only that portion of it that was directed towards the earth, the ratio of the lights was as 4 : 3. It appeared that the maximum illuminating effect of the alternate-current lamp was not, as frequently stated, in a horizontal direction; but that two cones of maximum illumination existed one above the other below the horizontal. The Committee reported, therefore, that equal amounts of energy gave 20 per cent. less useful lighting effect with the alternating-current both for outdoor and indoor lighting. On the other hand, the alternating current lamp required a lower tension, and a smaller resistance for regulation, and could consequently be run with 20 per cent. to 30 per cent. lower voltage; so that three of them could be run in series off a 105-volt circuit, instead of only two in the case of the direct-current lamp. The Committee reported that the buzzing noise observable with alternating currents was quite unimportant, as there was always a slight hissing even with direct-current lamps. The consumption of carbons was found with equal energy to be 20 per cent. higher in the alternating-current lamps; but as the cost of the carbon in 6 to 12-ampere lamps is only 10 per cent. of the total, this only means an increase of 2 per cent. on the whole cost. It was found that the cost of an 8-ampere alternating-current lamp was from 2·8 pence to 3·5 pence per hour, this size giving the same amount of light as a 6-ampere direct-current lamp costing 2·25 to 2·8 pence per hour; the larger sizes, taking 16 and 12 amperes respectively, cost from 5·2 to 6·5 pence in the case of the alternating-current lamp, and 4·1 to 5·1 pence in the case of the direct-current lamp. It was remarked that the alternations of current gave a multiple impression of objects in rapid motion, though on fixed objects the alternating-current light seemed perfectly steady.

Digitized by Google

Alternate-Current Meters.—Tests made with the Blâthy alternate-current meter showed that the instrument was correct within 3 per cent. for currents within the limits for which it was designed. In point of simplicity, size, cost, and sensibility it fulfilled all reasonable demands.

Alternate-Current Transformers.—The Committee reported that some tests undertaken by them showed that the efficiency of the Ganz medium-sized transformer was at full load 95 to 96 per cent., at half-load 93 to 94 per cent., at quarter-load 90 per cent., at one-eighth load about 80 per cent.

Direct-Current Transformers.—The Committee reported that they were not acquainted with any direct-current transformer that would answer the requirements of a central station. They could not recommend that which had been first proposed by Schuckert, and afterwards by Lahmeyer, in which both windings were on the same ring. They regretted that they had had no opportunity of testing such a transformer. The question of cost was not gone into, as none of the systems proposed for Frankfort involved the use of a direct-current transformer in the same way as the alternating-current schemes. The Committee called attention to the fact that the direct-current transformer, unlike that for alternating currents, contained moving parts, and therefore required constant attention. The efficiency of the direct-current transformer when working with full load was found to reach the 82 per cent. claimed for it by Messrs. Schuckert and Co. For less than full load the efficiency was not a matter of importance, as it was intended to use the transformer always at full load to charge accumulators. The loss on alternate-current transformers was only 5 or 6 per cent. as compared with this 18 per cent.

Accumulators.—With reference to accumulators, the Committee were asked whether any cell could be recommended for use on a large scale. Although on other questions they had been unanimous in their decision, on this point there were differences of opinion. Prof. Ferraris remarked that with regard to accumulators he had always been a pessimist. There had been numerous attempts at improving secondary cells, which proved the importance of the question ; but up to the present all expectations had been falsified. The Tudor accumulator gave good results on account of the method of making the plates, but this very process made it probable that they would completely break down after a time ; and he considered that a longer experience was necessary before deciding on its degree of merit. He did not consider that any system embracing so doubtful an element was to be recommended. Prof. Weber said that from the experience of the last few years he considered the lead accumulator had not improved much in efficiency. As regarded the life of the new Tudor cell, he thought an improvement had been effected in this direction, but it was impossible to say to what extent, as only two years' experience was obtainable, and from this no deductions could be made as to their probable state after ten years, the time for which the Company gives guarantees. He considered it a step in the right direction that Müller and Einbeck, of Hagen, undertook the maintenance of the cells. He would be pleased to see an accumulator plant installed at Frankfort, as it would afford an opportunity of watching the behaviour of accumulators employed on a large scale. Direktor Uppenborn did not see that the town would incur much risk, as the surplus of the subscribed fund could be applied to maintenance. He considered that all that was known of the action of the lead plates proved that their life would be sufficiently long. Prof. Kittler agreed with Direktor Uppenborn, but said he should have reported against the adoption of accumulators until the production of the Tudor type, which he was convinced showed great progress. He had proposed the use of accumulators for running machinery to the authorities at Darmstadt, where they had been working satisfactorily. He thought the substitution of wood for glass cells was an improvement, doing away with many chances of accident. He considered, therefore, that a town in using accumulators ran no risk either from a technical or a financial point of view.

The Five-Wire System.—As to the applicability of the five-wire system, the Committee reported that the first scheme of Siemens and Halske was not satisfactory, but that the second was more likely to satisfy requirements. As to the proposed tension of 440 volts, the Committee reported that the use of so high a voltage would necessitate great care on the part of the attendants. A disadvantage of the system was that the five distributing mains would each have to be laid separately, as under no circumstances would it be advisable to make up all the leads into one cable. Moreover, to ensure good regulation, it would be necessary in most cases to connect all five cables with customers' houses, which would be expensive. The Committee, however, stated that all these disadvantages were not so vital as to exclude the five-wire system where other circumstances rendered its adoption advisable.

Electric Traction.—With regard to traction, the Committee regarded a direct-current supply with overhead wire as out of the question for Frankfort ; an underground channel would therefore have to be used. If the traction current was supplied from the same circuits as the lighting current, the result would be a very bad effect on the lighting, owing to the variation of the demand for current for traction purposes at different times of the day and seasons of the year. This would be greatest on the winter evenings, just when the light was most required. For financial and practical reasons, it would, therefore, be well to separate the lighting and traction mains. It would, however, be advisable to adopt in each case the same class of current and the same voltage, so that in cases of accident interruption might be guarded against. For this reason both circuits should be worked from the same central stations. If the five-wire direct-current system were adopted, the pressure would suit traction work. If transformers (direct-current) were used, a subsidiary station could be employed. If the alternating-current was used, the traction systems might be supplied either from the exciting dynamos, or by means of transformers, using alternate-current motors. If, however, improvements in accumulators should warrant it, they would afford the surest and most satisfactory solution of the difficulty. It was concluded, therefore, that either system would serve equally well for the traction service.

Current for Electro-Chemical Purposes.—On the subject of distribution for electro-chemical purposes, the Committee reported that the demand for this was comparatively small, and that, the voltage required being very low, even with the direct-current system, a transformation would be necessary, so that the alternate-current and direct-current systems were in this respect on an equality.

On the whole question as to which of the two systems was to be adopted at Frankfort, the Committee found it difficult to arrive at a definite conclusion, owing chiefly to the fact that the suitability of this or that system depended largely on where the central station was to be, and whether water-power would be available ; and neither of these matters were then settled.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 23, 1890.

The Meeting of the American Institute of Electrical Engineers.—The event of the week on this side of the water has, of course, been the meeting of the American Institute of Electrical Engineers, which took place partly in New York and partly in Boston on Tuesday and Wednesday respectively. The annual business meeting was held in New York on Tuesday evening for the election of officers and the transaction of routine business. Prof. W. A. Anthony, of Manchester, Connecticut, was chosen President in place of the retiring Prof. Thomson, and Messrs. Francis B. Crocker, Frank J. Sprague and Joseph Wetzler, vice-presidents. The other officers chosen were as follows:—Managers: P. B. Delany, Horatio A. Foster, and J. C. Chamberlain; Treasurer: George M. Phelps; Secretary: R. W. Pope. The other officers of the Association hold over. It was reported that the total membership of the Institute is now 427, of which 12 were added at this meeting. At the New York meeting a Paper was read by Mr. Gilbert Wilkes upon "Electricity in the Navy," which gave considerable insight into the conditions necessary for electrical machines in naval service. At its conclusion many of the members of the Institute took the night train for Boston, where, on Wednesday morning, the meeting was continued in the building of the Massachusetts Institute of Technology. The Institute was welcomed by General Walker, who said that the Institute of Technology had felt it a privilege to entertain the mining engineers and other professional organisations, and that he was now glad to find electrical engineers as numerous and as welcome guests. Prof. Thomson responded on behalf of the Electrical Institute, after which the regular programme for the day was taken up. The first Paper was by Mr. Wilfred H. Fleming, of New York city, upon "Electric Lighting in the Tropics;" and the second upon "The Magnetic Data of the Sprague Street Car Motor," by Mr. H. F. Parshall. Dr. Louis B. Marks, of Cornell University, then discussed "Arc Light Carbons." Perhaps the most important Paper of the meeting was that upon "The Limitations of Steam and Electric Transportation," by Oscar T. Crosby, of New York city, which opened the afternoon session. Mr. Crosby has recently given some extremely valuable data concerning "Atmospheric Resistance

Digitized by Google

at High Speeds in Railway Traction;" and his present Paper, like that referred to, is the result of a long series of experimental tests in practical railroad work done under the auspices of the Weems Electric Railway Company. He spoke most encouragingly of the prospect of replacing steam by electricity, not merely upon city lines and for light work, but also for the most important uses to which railroading is now applied. His tables while conservative were elaborate and thorough, and show that the economical line dividing the present practice from that of the future is becoming so slight that electrical traction may soon be expected to replace steam on all important railroads. Other Papers read in the afternoon were by Dr. Michael J. Pupin on "The Practical Aspects of the Alternating-Current Theory;" by Mr. Thomas D. Lockwood, of Boston, on "The Industrial Utilization of the Counter Electromotive Force of Self-Induction;" and by Mr. Herman Lemp, Jun., on "Automatic Electric Welding Machines." Mr. Lockwood's Paper was historical in its nature and of very great interest, while Mr. Lemp's was accompanied by some extremely valuable experimental demonstrations. In the evening the Institute was sumptuously entertained by the Boston Electric Club at a dinner. Seven long tables were occupied by the members and guests, and no more noteworthy gathering of electricians has been seen in this country for a number of years past. After the dinner Mr. S. E. Barton spoke upon "The Relations of Electric Lighting to Insurance," and demonstrated to the satisfaction of those present that these relations should not be so strained as they at present seem. Other speakers were Prof. Thomson, Prof. Houston, Prof. Anthony and Mr. Pope; while Mr. C. F. Pritchard, President of the New England Association of Gas Engineers, extended the hand of friendship on behalf of the rival interests represented by him. Mr. Joseph Wetzler responded on behalf of "Electrical Journalism," and Senator Metcalf promised the goodwill of politicians and statesmen. On Thursday the Institute accepted the hospitality of various Boston electrical enterprises, and visited the power plant of the West End Tramway Company, one of the largest of its kind in the world, and also the great manufacturing works of the Thomson-Houston Electric Company at Lynn, near Boston. The meeting, although officially concluded on Wednesday, thus continued throughout the next day, and the interchange of ideas and informal discussion of Papers during the trips about town on Thursday form one of its most valuable features. It can safely be said that the experiment thus tried of holding a meeting of the American Institute of Electrical Engineers outside of New York city was eminently successful; and if the metropolis is to re-assert her claim to leadership in electrical matters she must look to her laurels next year.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *June* 4, 1890.

The Compagnie Continentale Edison has doubled the number of arc lamps lighting the Boulevard des Italiens, but the new lamps have not been placed in the middle of the road, as the old ones were, but have been arranged along the edge of the pavement. The lamp-posts are very handsome, being of the pattern adopted by the City of Paris for its large gas-burners. Owing to this new arrangement, the lighting of the Boulevard des Italiens is very brilliant; but these successive additions do not give so good a result as would have been the case if the installation had been completely planned at the outset.

The Société de la Transmission de la Force is actively pushing forward the work of laying underground mains. It is also making arrangements to place arc lamps along the pavements of the Boulevard Sébastopol, from the Boulevard Saint-Denis to the Rue du Caire.

The trials with the Cohen smoke-consuming furnaces, undertaken about five months ago at the Palais Royal central station, have proved very conclusive. The emission of smoke was very slight, and the consumption of coal was reduced by 20 per cent. These furnaces consist of an inclined grate, terminating in an external charging shoot; it is necessary to carefully keep this filled with coal, which then descends by its own weight as the fuel in the furnace is consumed. From time to time the stoker stirs the coal with a fire-iron to prevent it from accumulating at the entrance of the grate.

The foundation works of the central station of the Avenue de Vendaine commenced some days ago. The Compagnie Edison intends to push forward the station very quickly, and it has commenced to lay its mains in order that they may be ready directly the station is in a condition to commence operations.

A competition between various alternate current arc lamps is about to commence at the Halles Centrales. Amongst the lamps taking part in it I may mention those of Siemens, Pilsen, Clerc, Potier, Dandeux, &c. The Dujardin accumulator, which has so far given very good results, is going to be manufactured on a commercial scale. The question of accumulators is attracting considerable attention in France just at present, and it is probable that before long we shall have some really good and durable accumulators.

AUSTRALASIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

SYDNEY, *April* 20, 1890.

The electric lighting industry has received an impetus in this Colony during the last week, the Newcastle Council having decided definitely to adopt this system of illumination. To compete successfully with gas in the very home of coal is highly encouraging, and there is no doubt it will influence the progress of electric lighting in other parts of the Colony. The successful tenderers for Newcastle are Messrs. Kirkland and Co., who are to supply and erect plant for 1,500 lamps. The boilers chosen are the Babcock and Wilcox, with Westinghouse compound engines and Westinghouse electrical system. Moss Vale was lighted by electricity for the first time some weeks back, Messrs. Wood Brothers being the contractors. It is only a small continuous-current plant; the plain two-wire system is used, and the street lamps are of 16 candle-power. Messrs. Wood, Brothers, are using a newly-patented reflector, which is said to give good results. This firm have also on hand the lighting of the youngest suburb of Sydney (Enfield), the streets of which they have contracted to light with 16 candle-power lamps for £5 per annum, permission being granted them to supply private customers. Goulburn, one of the largest towns in New South Wales, some time since decided to accept the tender of Messrs. Kirkland and Co., for a central station for their town; but added a proviso to their acceptance, that it was subject to their being able to borrow the money. Now they appear to desire to rescind their resolution, and to wait a while. If they should do so, it will only be one more to add to the string of municipal councils who have played with electric light contractors. The Borough Council of Redfern are again considering the adoption of electricity as an illuminant; and this time, apparently, they are determined to carry it through, and they will probably call for tenders shortly. Ashfield, another of the Sydney suburbs, is also considering the matter; and should these places really adopt it, Sydney itself will, indeed, be behind the times, as, so far, the City Council do not appear in a hurry to go into the matter, and there are far too many obstacles in the way of private enterprise here to make it possible in that way.

The electric light has during the past week been of considerable service at Bourke, in which place the dangerous aspect of the floods necessitated an embankment being formed round the town; the Government, with foresight, forwarded a number of Brockie-Pell arc lamps to the scene of action, which facilitated the nightwork considerably.

At Lambton, the work in connection with the new central station is progressing favourably, and the contractors, Messrs. Kingsbury and Co., hope shortly to have the plant working. This firm also obtained the contract for lighting the Hotel Australia, one of the largest buildings in Sydney, being for an installation of 1,000 lamps.

The electric tramway question is one which at the present time is causing a good deal of argument here, opinions being somewhat divided between the electric and the cable systems. A report was received from Sir J. Fowler on the subject, and the said report has been severely criticised by the Sydney daily press. The general impression appears to be that more reliable information could have been obtained; Sir J. Fowler, being a civil engineer only, cannot, according to one paper, be taken as an authority as an electrical or mechanical engineer. The evidence given by Mr. Cracknell, the Government electrician, and Mr. Kopsch, of the telegraph department, before the Board of Works, is all in favour of the Thomson-Houston overhead system; and the only fear seems to be the question of what gradient can be successfully negotiated on this system.

We have amongst us now a new firm of electrical contractors, viz., the Williamson Electric Company, who have made their headquarters in Sydney, having taken offices in Pitt-street.

CORRESPONDENCE.

THE CROCKER-WHEELER ARC MOTOR SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to Mr. Firth's letter, which appeared in your issue of May 16th, respecting the above system. As my firm acts as European agents for the C. and W. system, and such a letter, if not replied to, may tend to create a wrong impression, I would say that Dr. S. S. Wheeler's complete specification was duly filed on May 7, 1889, in accordance with the International Patent Law, it being a complete specification previously deposited by him in the United States Patent Office as far back as June 9, 1888, which said patent, after careful examination by the Patent Office examiners, was accepted and issued in due course. Whereas, Messrs. Firth and Crabtree's final specification, as alluded to by Mr. Firth, was not filed until August 2nd following, and, in fact, not officially accepted by the Patent Office until November 2nd, or nearly six months after Dr. Wheeler's patent was granted, at which date, I may say, numbers of the C. and W. Motors were in full working order, including one exhibited by me at the late Birmingham Exhibition, and for which the silver medal diploma was awarded to the inventors. Therefore further comment from me on this point is unnecessary. It is easy to start a theory, but to start on entirely new lines and to make a practical and commercial success of a new invention is another thing altogether; but I can safely say that this has been successfully accomplished by Messrs. Crocker and Wheeler, and their associates, whose complete system for "electro-pulsion" I have no hesitation in saying is quite fundamental and unique, and the system is covered by about 30 patents taken out in various parts of the world, and covers large ground for many practical points of importance in connection with the electric traction industry. I therefore need say no more beyond apologising for taking up so much space in your valuable journal.—Yours, &c., ARTHUR SHIPPEY.

13 and 14, King-street, Cheapside, London, E.C.,
June 5, 1890.

PROTECTION FROM LIGHTNING IN RUSSIA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As everybody's thoughts are directed towards lightning and lightning conductors at the present time, I thought it might be interesting to note the effect of lightning in this part of the world, where all the buildings in the large towns are roofed with sheet iron, and the drain pipes terminate about a foot above the ground. Though thunderstorms are fairly frequent, it seldom or never happens that a house or other building in the town is struck, while in the country, where the cottages are covered with straw, it is an everyday occurrence. This seems to verify Prof. Oliver Lodge's theory.—Yours, &c.,

Moscow, May 16, 1890. LOUIS C. LOGAN.

THE LANE FOX PATENTS.

The following circular letter has been sent out to the trad by the Lane Fox Electrical Company:—

DEAR SIR,—1. As some misapprehension appears to exist in the mind of the public as to these patents, we wish to point out that they are at present held by the Lane Fox Electrical Company (Limited), subject to licences granted to the Brush Electrical Engineering Company (as successors of the Anglo-American Brush Electric Light Corporation), the Edison Swan United Company, and certain other persons abroad.

2. In the case of one patent, 3,988** of 1878, for distribution, Messrs. Crompton and Co., and the Swan United Company, have obtained an exemption from proceedings for infringement of the patents prior to December, 1882.

3. The Lane Fox Electrical Company (Limited) has been formed not merely, as has been alleged, to collect royalties; but to carry on a general electrical and incandescent lamp manufacturing business. If the Company is fairly met in the question of royalties but a small charge will be imposed, and it is anticipated that when the question is more fully understood, the reasonableness of the Company's charges will be appreciated by the industry.

4. It should be borne in mind that the Lane Fox patents are in no way invalidated by the long period during which they have been, or appear to have been, in suspense; nor, on the other hand, has that suspense been the fault of Mr. Lane Fox, or designed by him with a view of entrapping companies into their use.

5. At an early period the Lane Fox patents were disposed of by Mr. Lane Fox, to be worked with other patents, to the British Electric Light Company (Limited), and subsequently to the Anglo-American Brush Electric Light Corporation. Those who are conversant with the early history of electric lighting will know that until recently the principles of incandescent electric lighting were not generally understood; and though Mr. Lane Fox himself well knew the value of his patents, they were not properly appreciated by the companies who held them, and were mixed up and entangled with the claims of other patents held by the same companies for other and competing objects.

6. In illustration of the general contemporary ignorance of the principles now stated to be obvious, it may be mentioned that when first enunciated by Mr. Lane Fox they were received with ridicule and decried as impracticable, and that such staunch supporters of the system as Messrs. R. E. B. Crompton and W. H. Preece were at first opposed to them; even so great an authority as Sir William Thomson had for a time his doubts as to their theoretical soundness.

7. This opportunity may be taken to correct an impression which, to our great surprise, appears to prevail, namely, that Mr. Lane Fox confined himself some twelve years ago to shadowing forth the bare outlines of a scheme the essential details of which were laboriously worked out by others. This is not true. Not only were the principles of incandescent electric lighting distinctly enunciated by Mr. Lane Fox as stated above, but all details necessary to their efficient application were worked out by him independently, or through his agency, during the years 1878 to 1883. Thus in his hands the system became a thoroughly working system; installations were put up at home and abroad, and when Mr. Lane Fox temporarily abandoned electric work at the end of 1883, his system, which was ridiculed as late as 1881, was accepted and largely used.

8. After many abortive attempts to regain possession of the patents, attempts giving rise to "agreement" after "agreement" (each, as it was subsequently found, adding to, rather than removing the confusion), an agreement was finally come to upon the conclusion of the recent litigation between the Anglo-American Brush Electric Light Corporation and the Edison Swan United Company (Limited). By this agreement, dated December 3, 1889, each of the two litigating companies obtained a licence to use the patents in the future, and an indemnity in respect of the past; but, subject thereto and to certain licences affecting the foreign patents, all the patents were assigned absolutely to Mr. Lane Fox.

9. In February of this year the Lane Fox Electric Company (Limited) was formed to carry out the long-postponed designs of Mr. Lane Fox, and to vindicate his position as the inventor of the true principles of incandescent electric lighting. The Company, however, do not propose to charge vindictive royalties, or in any way to attempt to impede the progress already made, even by the unauthorised use of the Lane Fox patents.

10. Many times in the course of his prolonged negotiations with the Anglo-American Brush Electric Light Corporation Mr. Lane Fox was invited by competent financiers to join in the formation of a "ring" to control to their own exclusive advantage the electrical industry. Mr. Lane Fox declined. He wished to liberate and not to strangle the industry. Such still is his wish; and the wish of the Lane Fox Electrical Company is the same; but as true liberty consists in justice, and not in injustice, the Company will vindicate the patents, and insist upon the payment of royalties in respect of them.

11. In pursuance of this purpose the Company have formulated proposals, the terms of which will in due course be advertised; the pith of these proposals being that if those now using the patents will accept the proposed terms, or such modification of them as may be agreed upon by the middle of June next, no royalties will be claimed for the use of the patents prior to December 31, 1889.

12. It is confidently hoped that the companies and the electrical industry generally, will see the fairness and reasonableness of the terms proposed, and will co-operate in giving Mr. Lane Fox the position he can fairly claim in the electrical world.

(Signed) C. A. STEPHENSON,
Managing Director Lane Fox Electrical Company (Limited).

THE "TRENT" GAS ENGINE.

Simplicity of arrangement and reduction in the number of working parts have been the objects chiefly aimed at by the makers of this engine, the "Trent" Gas Engine Company of Nottingham. Even running, which is so essential in dynamo driving, is ensured by the reception of an impulse at every revolution. The engine has only one cylinder, one piston, and a single crank, like that of a steam engine, made of the best forged steel, and without any complicated levers or links of any kind. It has no slide-valves, or small easily choked ports. All motions are positive, actuated me-

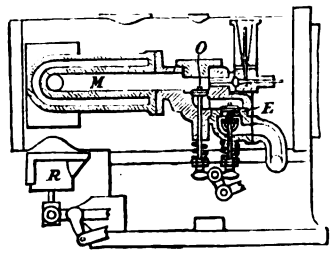

FIG. 1.—Elevation, showing the explosion chamber in section.

chanically and requiring no adjustment. As the gas is compressed to a relatively low pressure the engine is very easy to start. The explosion takes place outside the cylinder, in an explosion chamber, in which there is no working part. The most intense heat is, therefore, not on the piston, which consequently needs less lubrication

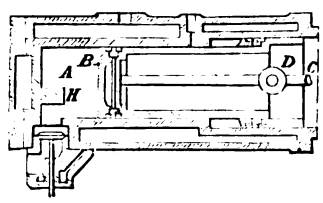

FIG. 2.—Vertical section of the engine.

and wears longer than is the case in other engines. The working parts consist of only the piston and three valves, all easily accessible and not subject to undue wear, and, excepting the exhaust valve, do not need any but the most occasional cleaning. The ignition, which is controlled by a small positive-acting valve, is re-

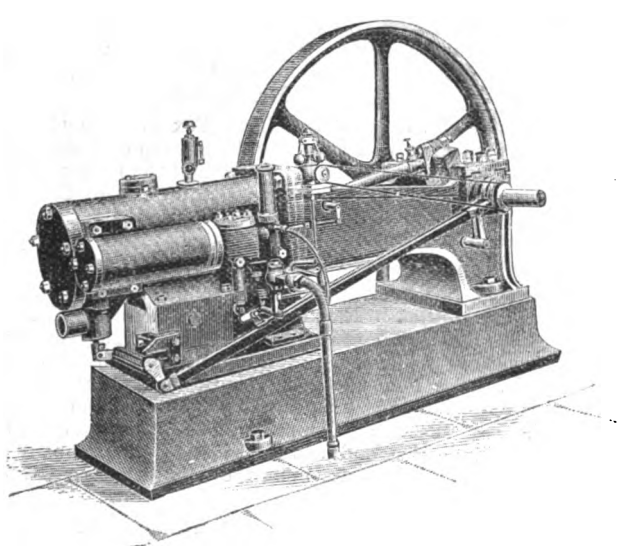

FIG. 3.—Perspective view of engine.

liable, and cannot take place prematurely. The exhaust gases escape at low pressure and therefore do not make any objectionable noise. We understand the Company are making 80-h.p. engines, having four impulses per revolution (quadruple-acting), especially for electric lighting purposes.

The following figures will help to explain the working of the engine :—A C is a cylinder of two diameters, in which works the double-headed piston B D. When the piston B D makes its out stroke, gas and air are drawn into the part C through a simple clack valve, E (Fig. 1). On the instroke of the piston B D, this valve is closed mechanically, and the mixture of gas and air contained in C is forced through the valve O (Fig. 1) into the explosion chamber M, where it is compressed (driving before it the exhaust gases remaining from the previous explosion, which escape through the valve R), and is then ignited. The resulting expansion impels the piston B D outwards. The acquired momentum of the fly-wheel performs the instroke.

Some recent tests of a four horse-power engine, by Mr. F. L. Guilford, gave a gas consumption per I.H.P. per hour of 17·6 cubic feet, and of 28·1 cubic feet per B.H.P. per hour ; and in engines of a later pattern these figures have been still further reduced.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—In our advertisement pages will be found particulars of the requirements of the Vestry of St. Pancras for works to supply electricity for a first installation of 10,000 16-candle power incandescent lamps, and for public lighting. There are seven contracts in all, which may be tendered for either wholly or in part, and in the event of any tender embracing more than one contract the amount of each must be separately stated. Drawings and specifications can be seen and full further particulars obtained at the offices of Prof. Robinson, 13, Victoria-street, London, S.W. The tenders have to be in before 4 o'clock on Monday, the 23rd inst., at the Vestry Hall, Pancras-road, London, N.W.

——— The Corporation of Swansea invite proposals from electric lighting companies for the execution and maintenance of all the works needed for the supply of electricity within the borough, in accordance with the Provisional Order obtained for the purpose by the Corporation. Copies of the conditions, Provisional Order, and lithographed plan can be obtained at the office of Mr. J. Thomas, Town Clerk, Guildhall, Swansea, on making a deposit of £5, which will be returned on receipt of a *bonâ fide* proposal. Proposals, endorsed "Electric Lighting," to be delivered to the Town Clerk by 30th inst.

——— The North-Eastern Railway Company invite tenders for the supply of (1) telegraph apparatus, and (2) telegraph wire and line stores during the six months ended December 31, delivered carriage paid at the Company's Telegraph Stores at York. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent to the Secretary, at York, sealed and marked "Tender for Telegraph Stores," by noon on 9th inst.

——— Tenders are required by the City of Brussels from persons willing to tender for the supply of electricity to the whole of the city, for a period of 25 years. Specifications may be obtained from the Secretariat, Hôtel de Ville, Brussels, to whom tenders, endorsed "Soumission pour Distribution d'Électricité," must be sent by noon on August 1st.

——— Tenders are required by the Magistracy of Copenhagen for the supply and setting up of steam boilers, engines, dynamos, leads, and all the necessaries for an electrical installation of 14,000 (simultaneously burning) incandescent lamps of 16 candle-power, with wiring for 20,000. Conditions and drawings, price 12s. each, can be obtained from the Magistracy of Copenhagen, 4th Division, with translation into the German and English languages. Tenders are to be in by August 1st.

SALE BY AUCTION.—Mr. R. Thorowgood announces the sale by auction, at the Mart, Tokenhouse-yard, London, E.C., on Monday next, of some valuable freehold property known as Horns Mills, Hertford, fitted with modern appliances, and possessing 20-horse permanent water-power and 32-horse steam-power, with a siding on the G.N.R., together with outbuildings and offices, a modern-built residence, and several acres of meadow land. Further particulars are given in our advertising columns ; and full descriptive particulars and plans may be obtained of the Secretary at the Mart ; of Messrs. Bowlings, Foyer, and Horden, solicitors, 26, Essex-street, London, W.C. ; at the *Midland Counties Herald* office, Birmingham ; and of the auctioneer, High-street, Ware, Herts.

DISSOLUTION OF PARTNERSHIP.—It is announced that Messrs. W. Blenheim and P. Holland, trading under the name of Messrs. W. Blenheim and Co., manufacturers of electrical apparatus, at Egham, Surrey, have dissolved partnership.

REMOVAL NOTICES.—Messrs. Cuttriss and Co. inform us that they have removed from 72, New Briggate, Leeds, into much more extensive premises at Elmwood Electrical Works, Camp-road, Leeds. This removal has been necessitated by the greatly increased demand for Messrs. Cuttriss's motors and dynamos, and the increased room at their disposal at their new premises will enable them to manufacture machines for heavy as well as light work.

Digitized by Google

REMOVAL NOTICES.—Mr. F. Geere Howard writes us that he has given up manufacturing, and intends devoting himself to contracting work only. He has removed from Cleveland Works to larger premises at 18, Berners-street, Oxford-street, London, W.

——— Messrs. S. A. Edwards and Co., importers of Swedish steel and iron, have removed from 6, Great Charles-street, to their newly-erected premises, 30, Easy-row, Broad-street, Birmingham.

A CARD INDEX TO CURRENT SCIENTIFIC LITERATURE.—The literature of applied science is scattered so widely amongst the British and Foreign technical and scientific periodicals, that it is well-nigh impossible for anyone to keep himself fully and *promptly* informed upon the most recent developments. With a view of assisting those who desire to keep abreast of the times the Newspaper Extract Agency, of 54, Charing Cross, has organised a special department on the reference card system.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

May 8, 1890.

7,186. W. P. THOMPSON. Liverpool. Improvements in welding metals electrically, and apparatus therefor.

7,196. H. GREFEN. London. An electric door lock.

7,209. L. SAUNDERSON. London. Improvements in electric arc lighting. (Date applied for under Patents Act, 1883, sec. 103, December 4, 1889, being date of application in United States.)

May 9, 1890.

7,219. J. PERRY. London. An electric supply motor.

7,225. T. J. BAKER. Stetchford, near Birmingham. Improvements in the construction of electric bell-pushes.

7,239. J. WOOLLEY and W. E. HUNNEX. Croydon. Improved switch for electric lighting.

May 12, 1890.

7,373. G. S. HOOKER. London. Improvements in electric switches.

7,378. A. BRÜLL. London. Improvements in electrical switches.

7,383. J. N. LEVSEN. London. An improved battery element.

May 13, 1890.

7,399. R. KENNEDY. Kilmarnock. Improvements in heating by magnetism and electricity.

7,422. F. BRYAN. London. Improvements in appliances used for protecting or regulating an electrical circuit.

7,425. M. S. CONLEY. London. Improvements in the method of producing alternating electric currents.

7,436. B. DUKES. London. Improvements in switches for electric currents (C. S. F. R. Bosse, Germany).

7,444. A. MILLION and P. BONY. London. Improvements in and relating to galvanic batteries.

7,456. A. DE BROUCHERE and L. ANSPACH. London. Apparatus for applying electricity to produce water-pressure for fire extinction or like purposes.

May 14, 1890.

7,473. W. B. SAYERS. Putney, Surrey. Improvements in electric incandescent lamps.

7,505. A. L. TAYLOR. Liverpool. New or improved safety devices for use with strong tensional electric currents for lessening fire risks.

7,511. M. IMMISCH. London. An improved brush for dynamos and motors.

COMPANIES' MEETINGS.

The Western Counties and South Wales Telephone Company (Limited).

The fifth annual ordinary general meeting of this Company was held on Monday, at the Grand Hotel, Bristol, under the presidency of Mr. Charles Nash.

The CHAIRMAN, in moving the adoption of the report, expressed regret at the absence of Messrs. J. S. Forbes and J. W. Batten (nominees of the National Company), in consequence of other engagements. It would be seen from the report that the capital expenditure to the end of 1889 was £139,593. 16s. 8d., and the gross revenue to the same date was £39,046. 19s. 6d. The whole of the preliminary expenses had now been cleared off, and not only had the plant been fully maintained and renewed, but it had in many cases been improved at considerable expense, by the substitution of the more efficient and durable copper and bronze wire for iron. The Directors felt some disappointment that the result of the year's work did not enable them to recommend a dividend on the ordinary shares; it was, however, proposed to add £500 to the special reserve fund, increasing it to £1,700. One principal cause of the small amount of net revenue was mentioned in the report, viz., the heavy necessary expenditure on trunk lines. The total expenditure on trunk lines up to the end of 1889 was, in round figures, £38,000, and this large outlay was only now beginning to be remunerative. It was gratifying to note that the use of the trunk system was increasingly popular amongst the Company's subscribers and the public. The increase in messages was not confined to Exchange subscribers and renters, but the outside public also largely used the call offices, the number of these latter calls having increased from 273 in December, 1887, to 1,772 in December, 1889, and to 1,968 in March, 1890. The total number of calls on the Company's trunk lines had been as given below, showing a monthly increase of 442 from September, 1887, to March, 1890:—

Total Calls on Trunks.

September, 1887	5,582
September, 1888	13,597
September, 1889	15,236
December, 1889	17,068
March, 1890	19,295

The calls last March were at the rate of more than 231,000 a year. Each call was answered, so that the number of communications had been at the rate of double these figures, or over 462,000. The cost of trunk lines to the end of 1886 was £11,009; 1887, £18,874; 1888, £29,823; 1889, £38,441; and the earnings of trunks per annum:—

December, 1886, at the rate of			£133
September, 1887	„	„	708
December, 1887	„	„	814
December, 1888	„	„	1,544
December, 1889	„	„	2,302
March, 1890	„	„	2,602

The increase of monthly earnings had been as follows:—September, 1887, to December, 1888 (16 months), £836 = per month £52 increase; January, 1889, to December, 1889 (12 months), £758 = per month £63 increase; January, 1890, to March, 1890 (3 months), £300 = per month £100 increase; thus the increase was progressive. Percentage of gross receipts on cost:— December, 1886, about 1¼ per cent.; December, 1887, 4¼ per cent.; December, 1888, 5¼ per cent.; December, 1889, 6 per cent. The large increase in calls during the current year gave confident promise of a further advance in this percentage. As yet the trunks had not been a direct source of profit, although the progressive increase in the monthly earnings, and the steady improvement in the percentage that the gross receipts bore to the cost, proved that they were no longer altogether unremunerative; but the indirect value of the trunk system in extending the Exchange business of the Company was very great. It was not merely in active business towns like Cardiff and Newport, where the calls amounted to several hundreds a day, that the value of the trunks was shown; but in quiet residential places like Bath, and in business places like Gloucester, where the value of the telephone to many of the subscribers was chiefly the power of communicating with Bristol, Cardiff, and other places; thus in many cases the trunk not only brought in its own revenue, but led to Exchange subscribers at each end. This experience made them anxious to extend trunks still further, as they were confident that many places which were at present quite unproductive would show a fair amount of business if connected

Digitized by Google

with one or more of their leading centres. Worcester, for instance, had been a disappointing place. After three unsuccessful attempts to establish an Exchange, they had now no subscribers there, but were confident that it would help materially when connected with Birmingham in one direction and with Gloucester and Bristol in the other. As many as sixty firms had promised to subscribe when the connecting; trunk was made and as arrangements were now complete for the connection with Birmingham, it might be hoped that in a month or two Worcester would yield a fair profit. They had lately opened an Exchange at Weston-super-Mare, and had already a fair number of subscribers, but they would not have obtained them without the promise of immediate trunk connection with Bristol. On completion of that line, which was now in a forward state, they looked for a large increase in the business at Weston-super-Mare. It was also important to complete the interval between Newton Abbot and Weston, bringing Exeter, Plymouth, and Torquay into direct communication with them. The effect of this would doubtless be to still further increase the Weston business, and that of Exeter and other places; and it would give the opportunity of opening Exchanges at Bridgewater, Taunton, and possibly at Wellington, Dawlish, and Teignmouth, with a fair prospect of business. Shrewsbury was another place where a trunk connection was much wanted. Salisbury was at present quite isolated; but by the construction of a trunk line from Bath, *viâ* Bradford, Trowbridge, Westbury, and Warminster, and continued to Winchester, these places would be put into direct communication with Bournemouth, Southampton, and Portsmouth, and with the whole of the Bristol and South Wales districts, and a fair amount of business would doubtless result. Without this trunk connection they had hitherto found it hopeless to establish an Exchange at Salisbury. With it they might expect fair business there, and probably at Trowbridge and other towns. A further extension of the trunk line from Winchester to the boundary of this Company's district near Reading, when met there as arranged for by the National Company, would place the whole of the principal towns in this district, as well as Bournemouth, Portsmouth, and Southampton, in communication with London, the effect of which could not fail to be very considerable. Another cause of the small net balance was that the auditors had adopted a different plan in dealing with some items of expenditure, charging a larger proportion to revenue than before. This was too technical a matter for explanation there, but it must be evident to every business man that, in an undertaking like theirs, with some parts of the system fully developed, others partially so, and others, again, only in an incipient state, it was only reasonable to expect a difference of opinion as to what portion of the expenditure was fairly chargeable to capital, and what applied to revenue. Another cause of the smallness of the balance was that during the year 1889 the progress of their Exchange and private line business was less rapid than in 1888. The increase in ordinary receipts in 1888 was £99 per week, and that for 1889 £74 per week, making a difference of about £1,300 in the year. It was not easy to account for this, but it was certainly not to be taken as a sign that the use of the telephone had nearly reached its limit, for during the present year the advance at several of their large centres had been very rapid. For instance, Bristol had increased at the rate of £11 a week, against £7 a week last year, and Cardiff at the rate of £18 a week, against £13 last year. During the first twenty weeks of this year, as compared with the same period last year, the increased receipts from all their Exchanges and private lines had averaged £90 per week, and during the last five weeks as much as £104 per week, so that, without venturing to look into the future, they could state as a fact that the Exchange and private line business of the first five months of the current year showed a decided improvement on 1889, in addition to the excess of income on trunks already referred to. On the whole, with the improved state of general business, and the adoption of the telephone in all parts of the world, and in many to a much greater extent—as in America, where there were stated to be 300,000 telephones at work—he could not doubt that its use would be greatly extended in this country. There was certainly no reason to be discouraged, for the telephone was now a necessity at their public offices, to police and fire brigades, wholesale and retail merchants, so that as fresh towns were connected by trunk lines there would doubtless be a great extension in its development. But the usefulness of the telephone was not limited to these classes, as was proved by their own experience:—Thus, at Portsmouth they had 16 hotels connected, at Torquay 11, and at Bournemouth, including boarding-houses, 27; in Bristol and Clifton they had 2—the Grand and the Clifton-down Hotels. Why was this? Again, at Bournemouth they had 20 doctors on the Exchange, and at Plymouth (the three towns) there were 20; in Bristol *nil*, and 3 in Clifton. Private residents were another large class that had only partially availed themselves of the telephone. In proportion to population Torquay took the lead with 35, Bournemouth had 24, and Plymouth 38. At most of their other Exchanges there were very few private resident subscribers. These figures showed that there were large classes that had as yet failed to realise the advantages of the telephone; and he did not doubt that, if more of their large retail businesses were connected, many more private residents would find it to their advantage to subscribe. There was still much ground unworked. For instance, Falmouth and Truro were now asking for an Exchange, and many other towns might by degrees desire not to be left out of a system which was spreading over the country.

Mr. H. FEDDEN seconded the resolution.

Colonel SAVILE supported the resolution. For so young a Company he felt the dividend they had earned was satisfactory. The business seemed to be growing and increasing in a way they could scarcely have expected. He did not see any charge for the Directors' fees in the balance sheet for the past year. They ought not to expect them to work for nothing, and at a later stage of the meeting he should move that the sum of £500 be paid to the Directors by way of remuneration.

The SECRETARY explained that they could not insert that sum in the balance sheet without the sanction of that meeting.

The Report was then adopted.

The CHAIRMAN then moved—

"*That a dividend of 6 per cent. per annum upon the amounts paid up on Preference shares to the 31st of December, 1889, be declared, and that the amounts already paid by the Directors on account of such dividend, being the whole amount, be approved and confirmed.*"

Mr. R. CORY seconded the motion, and it was carried.

Mr. READ proposed the re-election of Mr. Thos. Pole, one of the retiring Directors; and the proposition was seconded by Mr. W. WHITE, and adopted.

Mr. READ moved, and Mr. WHITE seconded, the re-election of Mr. Henry Fedden, the other Director who retired. This motion was carried.

The CHAIRMAN proposed the re-election of the auditors, Messrs. Hudson, Smith, Briggs, and Co.

Mr. R. CORY seconded the resolution, which was adopted.

The CHAIRMAN moved that the sum of £500 be added to the reserve fund, making a sum total of £1,700.

Mr. M. WHITWILL seconded the resolution, which was adopted.

The remuneration of the auditors for the year 1889 was fixed at 95 guineas, this proposition being submitted by the CHAIRMAN and seconded by Mr. READ.

Col. SAVILE moved, and Mr. W. WHITE seconded,

"*That the remuneration of the Directors be fixed at the sum of £500 for the year 1889.*"

The motion was unanimously agreed to.

The meeting was then made an extraordinary one, for the purpose of making verbal alterations in the Articles of Association caused by the National Telephone Company (Limited) taking the place of the late United Company in certain contingencies.

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

These alterations were proposed by the CHAIRMAN and seconded by Mr. CORY, and were agreed to, and the confirmatory meeting was fixed for that day four weeks.

Mr. FEDDEN proposed a vote of thanks to the Chairman ; and this was unanimously passed.

The CHAIRMAN, in acknowledging the resolution, said he did take a great interest in the Company ; but he must not omit to say that Mr. Lewis, their energetic manager, was the mainstay of the concern, and they must thank him for his continued exertions on the Company's behalf.

NEW COMPANIES REGISTERED.

BISHOP'S STORTFORD ELECTRIC LIGHT AND STEAM LAUNDRY COMPANY (LIMITED).—This Company was registered on the 28th ult., with a capital of £10,000, in £1 shares, to carry on at Bishop's Stortford, or elsewhere, the business of electric lighting, and also of a steam laundry. Registered without special articles. Solicitors: Messrs. Acklands and Nockolds, Bishop's Stortford.

"THE ENGINEER" COMPANY (LIMITED).—This Company was registered on the 24th ult., with a capital of £160,000, in £100 shares, to purchase the *Engineer* newspaper. The subscribers are :—C. A. Close, Harrow, solicitor ; V. Pendred, C.E., 19, Pendennis-road, Streatham ; D. L. Holmes, 16, Cornwall-gardens, barrister ; J. J. Stansfield, B.A., 41, Ladbroke-square ; S. White, Babington-road, Streatham, publisher ; J. A. Edwards, 164, Brompton-road, accountant ; W. R. von Glehn, 22, Campden-hill-gardens, merchant. The number of Directors is not to be less than 3, nor more than 5 ; the subscribers are to appoint the first. Qualification, 30 shares. Solicitors : Messrs. Close and Co., 23, Great Marlborough-street.

RATCLIFFE AND HORNER (LIMITED).—This Company has been registered with a capital of £20,000, in £10 shares, to carry on a business as mechanical engineers, machine and engineering tool makers, boiler makers, safe manufacturers, iron founders, &c.

CITY NOTES, &c.

THE ALUMINIUM INDUSTRIE GESELLSCHAFT OF NEUHAUSEN.—From the *Electrotechnischer Anzeiger* we learn that the Aluminium Industrie Gesellschaft of Neuhausen has paid a dividend of 4 per cent. on its capital, besides writing off 177,356 francs as a sinking fund for the patents in its possession, the latter now only standing at 34,228 francs in the Company's books.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The Directors of this Company have declared an interim dividend of 3s. per share, free of income-tax, being at the rate of 6 per cent. per annum, for the quarter ended March 31st last, and payable on the 24th inst. The books of the Company will be closed from the 17th to the 23rd inst., both days inclusive.—The receipts for the week ended May 30th amounted to £4,171.

COMMERCIAL CABLE COMPANY.—This Company has declared a quarterly dividend of 1½ per cent., payable July 1st. The transfer books will be closed from the 20th inst. until July 2.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of May were £3,400, as compared with £3,513 in the corresponding month of last year. The receipts for the month of February, estimated at £3,300, realised £3,391.

DICK, KERR, AND CO. (LIMITED).—The prospectus has this week been issued of Dick, Kerr, and Co. (Limited), with a capital of £160,000, in 32,000 shares of £5 each, made up of 16,000 Seven per Cent. Cumulative Preference shares and 16,000 ordinary shares. The prospectus provides that not less than one-fourth of the surplus profits shall be placed to a reserve fund until such fund amounts to £61,500. Out of the balance of profits the ordinary shares are to receive 7 per cent., and the surplus, after deducting 10 per cent. additional remuneration for the Directors, is to be divided equally between both classes of capital. The present issue is made under the auspices of the Trustees, Executors, and Securities Insurance Corporation (Limited), and is for the Preference shares only at par, payable—10s. per share on application, £1 on allotment, £1. 10s. on June 25th, and £2 on July 31st. The Directors include Major-General C. E. Webber, C.B. The Company is established to acquire and develop the engineering and contracting business carried on by Messrs. Dick, Kerr, and Co. at Kilmarnock and London. As our readers are aware, the firm has an acknowledged reputation for the supply and manufacture of tramway permanent way material, portable railway and rolling stock, railway permanent way material, cable tramway machinery, cable tramways, gas engines, &c. The Secretary of the Company is Mr. G. W. Carr, and the offices are at Leadenhall House, London, E.C. The lists of application closed yesterday (Thursday).

DIRECT SPANISH TELEGRAPH COMPANY.—The receipts of this Company for the month of May amounted to £2,244, as compared with £2,040 for the corresponding period of 1889, showing an increase of £204.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of May amounted to £53,373, as against £52,704 for the corresponding period of 1889, or an increase of £669.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of May were £41,230, as against £41,064 in the corresponding period, showing an increase of £166.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company are as follows :—Receipts in May, 1890, £24,000 ; January 1 to May 31, 1890, £105,800. Corresponding months in 1889, £106,800 ; ditto in 1888, £108,400.

GREENWOOD & BATLEY (LIMITED).—The second annual ordinary general meeting of Greenwood and Batley (Ltd.) was held on Thursday at the offices, 16, Great George-street, Westminster, under the presidency of Mr. Arthur Greenwood, who stated that the result of the first year's operations of the Company had been fairly satisfactory, whilst there was every prospect of the present year being a good one. A motion for the adoption of the report and the statement of accounts, and the declaration of a dividend at the rate of 7 per cent. per annum on the Preference shares and 10 per cent. per annum on the ordinary shares, was unanimously agreed to ; and the meeting having been made extraordinary, it was resolved, on the motion of the Chairman, to make a further issue of the capital of the Company to the extent of £44,000, viz., £16,000 in Seven per Cent. Cumulative Preference shares and £28,000 in ordinary shares, to be offered (as the report stated) in the first instance *pro ratâ* to the shareholders at moderate premiums.

NORWICH ELECTRICITY COMPANY (LIMITED).—The first general meeting of this Company was held recently under the presidency of the Chairman, Mr. F. W. Harmer, who said that as the requisite Parliamentary authority to supply electricity upon a large scale in Norwich cannot be obtained until next year, the Directors would take advantage of the delay by profiting by the experience of other towns in the erection of central station works, and by obtaining the latest improvements in electric plant.

PHŒNIX ELECTRIC LIGHT AND POWER COMPANY.—From the liquidator's report, to be put before the shareholders on the 30th inst., it appears that the money received, including £125 from the vendor, "in settlement of claim for return of purchase-money," amounts to £1,617. 4s. 10d. Out of a total list of debts and claims sent in, amounting to £25,105. 17s., £659. 13s. 1d. were admitted, and these have received 3s. 9d. in the pound. This absorbs £123, which is the total available for distribution out of the £1,617. 4s. 10d. obtained by liquidator's hands.

STOCK EXCHANGE.—Application has been made to the Committee to appoint a special settling day in the ordinary shares of the Notting Hill Electric Lighting Company (Limited).

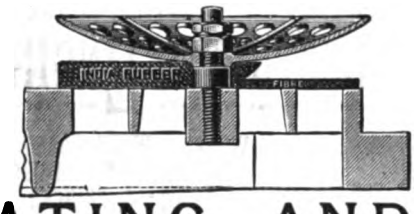
WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended 30th May, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,262.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month ended 31st May amounted to £6,075.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended May 31st show an increase of £131, as compared with the corresponding period.

WESTERN UNION TELEGRAPH COMPANY (LIMITED).—This Company has acquired the telegraph lines of the San Antonio and Aransas Pass for $100,000. The Company has also secured control of the Roy State Railway Telegraph Company for 99 years.

NEW VALVE



No Rubber, Percha, or Leather.

One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 630.—Vol. XXV. FRIDAY, JUNE 13, 1890. Price Fourpence.

NOTES.

Whatever may be thought of the Pacific cable scheme, of which Mr. Harold Finch Hatton is the exponent, his appearance as a competitor of Mr. Henniker Heaton for the distinction of having reduced the cable rates to Australasia is a welcome relief to the monotony of the last-named gentleman's pertinacity. It will be pleasant pastime to see the two rival claimants fight it out between themselves. Meanwhile, to all sensible people it must be evident that neither of these self-constituted instruments of intimidation has exerted the least practical influence on the action of the Eastern Telegraph Cable Companies, the simple fact being that propositions which the Companies long ago voluntarily put forward have now at length been accepted substantially by the Governments concerned. The rates will probably be reduced in consequence, by way of experiment; and Mr. Henniker Heaton's share in the business appears to amount to this, that he somehow or other got to know that the Australasian Agents-General were about to consent to the Companies' propositions, and was able to telegraph to Australia to that effect a day or two before the decision was made publicly known.

The opposition which was offered to the third reading of the Central London Railway Bill on Friday evening last was not of a very effective character, either as regards the arguments brought forward or the results obtained. It is satisfactory to find that this attempt to delay a great and necessary public improvement met with scant support in the House of Commons; and it is to be hoped that the Bill will be allowed to pass through its remaining stages without further opposition. It is proverbially rash to prophesy; but it does not require much hardihood to predict that the West End shopkeepers—to whom this persistent opposition is mainly due—will benefit as much as any section of the community by the general introduction of electric traction.

A description of the new Westinghouse arc-light system was given in our issue of the 25th April; and we are now able to publish a more detailed account of the method of constant-current regulation adopted in this alternating system. Transformers regulating for constant potential are so exclusively used that the properties of those regulating for constant current seem at first surprising. Thus, short-circuiting the secondary of a converter appears a startling method of putting it out of circuit; yet, by so doing, the potential absorbed is reduced to a minimum, and the energy wasted is very small. The series of transformers in circuit with the alternator must be regarded as a non-inductive resistance, owing to the effect of secondary currents, which, since the converters are short-circuited when not in use, are always able to practically neutralise the magnetising effect of the primary current. The lag of the current behind the E.M.F., caused by the very high self-induction of the armature, is diminished as the load is increased, owing to the increased ratio of the resistance to the self-induction; and by arranging that as the lag diminishes the neutralising effect of the armature current on the field is rendered less important, the E.M.F. of the machine is made to increase in proportion to the load. The system is peculiarly adapted for arc lighting, owing to the rapid rise of potential if the current diminishes. The use of resistance coils in series with the lamps, which are necessary on constant-potential circuits, is thus avoided. The method of regulation appears to be very successful, and the possibility of completely separating the lamp circuits from the high-potential mains is a great advantage. It is, indeed, a curious commentary on the generally accepted belief that the use of alternate currents necessitates greatly increased safeguards against danger to life, that the Westinghouse Company should now be introducing a system for series arc-lighting, in which, by the use of alternating currents, an immunity from danger is secured impossible of attainment in continuous-current high-tension systems.

This self-regulating alternate-current generator brings to mind the machine described by Mr. Mordey in his Paper on "Alternate-Current Working." It will be remembered that during the discussion Prof. Forbes, who had been independently at work on a similar machine, stated that "the self-induction of the machine in the form in which it was made was enormous, and the variations in volts when the different strengths of current were taken off were something perfectly surprising—in fact, you might almost say that the current was constant."

From a map of the North of England district of the National Telephone Company which lies before us, the National Company appears to have covered this busy part of the United Kingdom with a very complete network of trunk wires. Taking Manchester as the centre of the system, the lines branch out in all directions, to Liverpool, Leeds, Bolton, Brad-

Digitized by Google

ford, and Blackburn; and southwards to Sheffield and Nottingham; and we trust that before many more months have elapsed we shall witness the completion of that long-promised trunk wire to the north, placing the metropolis in direct telephonic communication with the great industrial towns of Lancashire and Yorkshire. The Western Counties and South Wales Telephone Company is also actively extending its trunk system; and at the recent general meeting of this Company the Chairman expressed a hope that London would soon be in connection with the principal towns of the south and west. Although the greater part of the district served by the Western Counties Company can scarcely be termed a valuable one from the inter-urban telephonic point of view, yet the direct return upon that Company's large outlay on trunk lines is very encouraging. If the receipts from inter-urban messages continue to increase at their present rate, these trunk lines will confound the prophets by proving themselves self-supporting, though doubtless their indirect value will always remain their true *raison d'être*. When these ambitious projects are fully realised, a thorough overhauling of the metropolitan system should be the next item on the programme.

At the meeting of the Physical Society on Friday last Mr. H. Tomlinson drew attention to a remarkable influence of temperature on the Villari critical point of iron. It appears that at ordinary temperatures there are, for a given magnetising force, two values of the load at which a Villari critical point occurs, and that as the temperature rises these values approach each other until at high temperatures no critical point exists. As with the other effects of temperature on magnetisation no explanation appears at present possible; but the very definite results of this investigation may hereafter be of value in testing new theories.

At the same meeting Prof. Rücker read an important Paper by two of his students, Messrs. Robson and S. W. Smith. The subject treated was the diurnal variation of the magnet at Kew, and the result of the work will probably have great influence in deciding the manner in which the mean value of the diurnal variation is calculated in magnetic observatories both at home and abroad. The work of the authors, taken in conjunction with that of previous investigators, conclusively shows that the mean value calculated from observations taken on five selected days of the month, differs only slightly, and in a determinate manner, from the mean value calculated from practically all the observations taken during the month. The great expense necessary for the complete calculations is thus to a large extent avoided; and as most observatories can afford the expense of the simpler method, while only a few, such as the one at Greenwich, are competent to carry out the complete calculation, the result will be that a much greater collection of statistics will be annually added to the data from whose study we may hope in future to learn the explanation of terrestrial magnetism. This is more especially the case as there seems reasonable ground for hope that the various observatories may be induced to perform the calculations on a common plan.

An Electric Organ.—The fine organ of Nôtre Dame has just been fitted with electro-pneumatic appliances.

The Imperial Academy of Sciences.—Lord Rayleigh has been elected a corresponding member of the Imperial Academy of Sciences, Vienna.

Personal.—Mr. Albion T. Snell, M.I.E.E., M.I.C.E., has been appointed works manager and chief engineer to the General Electric Power and Traction Company (Limited).

The North Metropolitan Tramways Bill.—The Unopposed Bill Committee of the House of Lords passed this Bill on Friday last. The Bill has now received the sanction of both Houses.

Gas and Electricity.—At the meeting of the Gas Institute next week at Ryde, a Paper by Mr. A. F. Guy, entitled "Shall Gas Undertakings supply Electricity? Yes," is down for reading.

Manchester.—The compulsory area of supply adopted by the Gas Committee of the Corporation for inclusion in the Provisional Order for the electric lighting of the city is about 393 acres in extent.

Honours.—The President of the Republic of France has, by request of the Académie des Sciences, conferred on Prof. Sylvester and Prof. Cayley the "decoration" of an officer of the Legion of Honour.

The Central London Railway Bill.—The Queen's consent on behalf of the Crown to the Central London Railway Bill was signified and the Bill read a third time in the House of Commons last Wednesday night.

A Central Station Struck by Lightning.—The Manhattan Electric Lighting Company's station in Eightieth street, New York, was set on fire by lightning on Tuesday last. The loss, it is estimated, will amount to $60,000 (£12,000).

Strike at Messrs. Ganz and Co.'s Works.—The *Elektrotechnischer Anzeiger* states that a strike has broken out at Messrs. Ganz and Co.'s, originating, it is said, with the foreign workmen. An advance was asked for but not conceded.

Royal Society.—Among the Papers down for reading yesterday at the Royal Society was one by Dr. Beevor and Prof. Horsley, F.R.S., "A Record of the Results obtained by Electrical Excitation of the so-called Motor Cortex and Internal Capsule in an Ourang Outang (*Simia satyrus*)."

Stockton.—With regard to the Provisional Order just issued to the Corporation, the charge proposed to be made is 13s. 4d. for any amount up to 20 units, and for each unit over 20 units 8d. It has been decided to apply to the Local Government Board for sanction to borrow £25,000 for electric lighting.

Electric Launches at Edinburgh.—The result of the first week's running of the electric launches on the Union Canal to and from the Edinburgh Exhibition has proved highly satisfactory. Some days only two boats were on the service, and the weather was unfavourable, but the receipts amounted to £100, and 6,500 passengers were carried.

Institution of Civil Engineers.—The name of Mr. C. H. Wordingham should be added to the list (*The Electrician*, June 6, p. 109) of those who obtained awards for communications submitted during the past session of this institution. Mr. Wordingham obtained a Miller Prize for his Paper on "Telephonic Switching," read at a Supplemental Students' Meeting.

Electric Traction in Liverpool.—Having obtained permission from the Health Committee of the Corporation, an accumulator car left the Walton depôt of the Liverpool Tramway Company early on Monday morning and made the round trip to the pierhead. The experiment was made under the guidance of the Electric Traction Company's engineer, Mr. Thomas Frazer.

Welding by Electricity.—Some electric welding experiments were shown on Tuesday at the works of Messrs. Clarke, Chapman and Company, Gateshead, to an interested company. The operations were conducted under the supervision of Mr. F. C. Fish, electrical engineer for the Welding Company, and Mr. Boland, representative of the American proprietors of the patent.

Digitized by Google

The Mariotti Multipolar Dynamo.—The Société des Téléphones de Zürich have just brought out a dynamo designed by their chief engineer, M. Mariotti. The machine is of the multipolar type, with a ring armature embraced alternately by external and internal pole-pieces. Some tests with a 20 horse-power dynamo of this type are said to have yielded very satisfactory results.

Ipswich.—At a recent meeting of the Ipswich Paving and Lighting Committee, a communication was read from the Brush Electrical Engineering Company notifying that, in consequence of a technical irregularity in the form of notice given, the Board of Trade had decided not to deal with their application for an Order this year. Therefore the Company would not be able to take steps to provide electric light for the present; but intended to renew the application in proper form for next Session.

Foreign Contracts.—In a Parliamentary paper just published, a return is given of all contracts for articles of home manufacture between April 1, 1889, and March 31, 1890, with contractors outside the Kingdom. The contracts thus entered into by the Admiralty were for carbons for electric light, £228; Mangin mirrors for electric light projectors, £11,236—total, £11,464. The only other department which entered into such contracts was the Post Office, which in this manner spent £1,016 on Hughes' telegraph instruments.

The Lane-Fox Patents.—In a circular letter which the Lane-Fox Electrical Company is sending out to all "undertakers" using the Lane-Fox system of distribution, the royalties demanded are 50 per cent. less than those which it was originally intended to enforce (*Electrician*, May 30th). The amounts are now: (1) ½d. per Board of Trade unit supplied; (2) ⅛d. per Board of Trade unit supplied, such payment to continue after the expiration of the patent for such a term as would render it equivalent to No. 1. In respect of private installations, a circular will shortly be issued proposing a payment of 3s. 6d. per annum per 16 candle-power lamp.

Overhead Wires.—In the House of Commons on Monday night Mr. Dixon-Hartland asked the Attorney-General whether the new electric-light companies in London were legally empowered to disfigure the streets and greatly increase the risk of fires by putting their wires overhead instead of underground. —The Attorney-General replied that under the Electric Lighting Acts of 1882 and 1888 powers are reserved to the County Council and to the Board of Trade for regulating and controlling the cases in which overhead wires may be used, and, in his opinion, these powers were sufficient. The information before him did not tend to show that overhead wires increased the risk of fires.

The International Telegraph Conference.—We are informed that notification has been given by Mr. Fuller and Major Wood, the respective representatives of the Brazilian Telegraph Cable Companies, that a reduction of 50 per cent. will be given from the 1st July next for Press messages (subject to the usual regulations governing the transmission of this class of correspondence) to and from the East Coast of South America.—It is expected that the Conference will conclude its labours on the 18th or 19th inst. The Telegraph Companies entertain the French Minister of Commerce, of Industry, and of the Colonies, and all the Delegates to the International Telegraph Conference, at breakfast, on Tuesday, the 17th inst., at the Hotel Continental, Paris.

St. Austell.—The low-tension station which was opened at St. Austell in 1887 by Mr. J. E. Veale now supplies between 50 and 60 shops, hotels and private houses. Several high candle-power incandescents are employed, and at the Congregational chapel a small electric motor is used for blowing the organ. As a striking illustration of the advantages of electricity as a motive power, it may be mentioned that a St. Austell tradesman, whose premises were lighted by electricity, recently received an urgent order for the making of a large tent cover. A small electric motor was hired from Mr. Veale's works, and the machine was worked by this motor. By this means an order was executed which could not otherwise have possibly been completed in time.

St. Martin's Vestry v. Gordon.—In the Court of Queen's Bench on Saturday a matter was decided, by the Lord Chief Justice and Mr. Justice Wills, of some importance to those using electricity for lighting and other purposes. The St. Martin's Vestry, who were the appellants, appealed against a decision of the police magistrate at Bow-street. The point at issue was whether the clinkers from the furnaces in the basement of an hotel, of which Mr. Frederick Gordon was the proprietor, was trade refuse, for the removal of which payment might be demanded. The boilers were used to generate steam for electrical purposes. Their lordships held that the clinkers were not trade refuse, and dismissed the appeal, giving leave, however, to the appellants to further appeal if they were desirous of so doing.

An Electric Call System for Boy Messengers.—The Boy Messenger Company, which has now been in successful operation for about three years, is about to organise a system of electric calls, to enable customers to signal from their own office or private residence for a messenger; and they are seeking to obtain a licence from the Postmaster-General for such a system of electric signals as would meet their needs. With a view of obtaining an expression on the part of the public in favour of the system in order to satisfy the Postmaster-General of the extent of the demand for it, a memorial is being extensively signed by all sections of the London public. The petition can be signed at any of the following places, viz:—Star-yard, Carey-street; 139, Oxford-street; 9, Bridge-street, Westminster; and 36, Gresham-street, E.C.

Bristol.—At the last meeting of the Corporation, the Mayor moved "That the Council do adopt experimentally the alternate-current transformer system of lighting in the area included in schedule A of the Bristol Order, confirmed by the Electric Lighting Orders Confirmation (No. 9) Act, 1883." Mr. A. Baker said it seemed to him that the Electric Lighting Committee had not carried the matter so far as they ought to have done. Electric lighting was no longer a matter of experiment; and he moved as an amendment, "That it is desirable that the Corporation should keep the control of the supply of electricity for lighting and other purposes of the city in its own hands, and that the report be referred back to the committee, with instructions to advise the Council as to the desirability of adopting a scheme for lighting a larger area than that suggested, and for supplying private consumers with electricity." After a long discussion, the amendment was carried by 33 votes to 5.

Artistic Electric Lighting.—In his new house at 1, Queen's-gate-gardens, Mr. J. E. H. Gordon has, as might have been expected, made the utmost of the artistic possibilities of the electric light. The house is provided with about 115 lights, many of which are of high candle-power, and the fittings not only exhibit great originality, but are also of great variety. In the drawing-room for instance, the ceiling of which is panelled with gold Japanese embroidery, the room is illuminated by reflection, the light being thrown against the ceiling by four high candle-power incandescent lamps, beneath which is placed a mass of muslin held up by figures of flying storks. In another part of the same room a window of Cairene lattice work is lighted from the outside in the most artistic fashion. Wall plugs have been extensively employed, and it is possible to obtain the current for a portable lamp in almost any part of the house. The whole of the electrical fittings were carried out by Messrs. Faraday and Son, and the current is obtained from the Kensington Court mains, and the supply has given every satisfaction.

Obituary.—The death is announced on the 29th May of M. Daniel Napoli, head of the laboratory of the Eastern Railway Company of France. Born at Naples on the 27th April, 1840, M. Napoli came to Paris at an early age, and entered the employment of the Eastern Railway Company, as an apprenticed fitter, where his intelligence and great manual skill soon attracted attention. In the field of electricity M. Napoli was the inventor of several skilful contrivances, such as electric clocks and electric alarms. To him also were due some ingenious devices connected with the Regnier-Werdermann lamp. He took an active part in organising the first Electrical Exhibition of

Digitized by Google

1881; and his work in connection with the Association Polytechnique gave valuable aid to the popularisation of science. M. Napoli was no mean sculptor, and several of his works found a place in the *Salon*; amongst which were busts of Ampère, Gramme, and Graham Bell. He was Chevalier of the Legion of Honour, officer of the Academy, President of the Société de Navigation Aérienne, and "Secrétaire-fondateur" of the Société Internationale des Électriciens.

Folkestone.—At the last meeting of the Town Council a lengthy discussion ensued on the reading of the report of the Electric Lighting Committee. From this it seems that the Corporation having objected to the streets being opened before October 1st, Messrs. Crompton and Co., the electric light contractors, stated that they could not get the light ready by January 1st. It was therefore resolved by the Committee that the Corporation should be recommended to alter the date for the commencement of the work in the streets from October 1st to August 1st. To this the contractors replied that if they could commence at once they would be ready with the light by January 1st; but as there would be some further delay, they felt it better to say at once that February 1st should be fixed as the day on which the lighting should commence. In reply to a further communication from the Committee the contractors said they could not now promise to be ready before February 1st. Mr. Thompson moved that the report of the Committee and the letter from the Company be received, and referred back to the Electric Lighting Committee, with power to arrange with Messrs. Crompton and Co. as to the date at which public lighting shall commence, and matters incident thereto. After great discussion Mr. Thompson's resolution was carried, subject to an instruction that the streets were not to be interfered with before October 1st.

The Australian Cable Rates.—Acting upon instructions recently sent to them by their Ministries, the Australian Agents-General had an interview, on Friday last, with the Financial Secretary to the Treasury, for the purpose of proffering the request that the Home Government should bear a share of the subsidies and guarantees granted by the Colonial Governments to the cable services from Great Britain to Australia, which subsidies will be considerably increased when the reduced rates come into force next January. Mr. Jackson is understood to have assured the colonial representatives that their views should be laid before Mr. Goschen, and that the matter would receive most careful consideration.—In the House of Commons on Monday night Mr. Summers asked whether, with a view of improving and cheapening communication between the different parts of the British Empire, the Government would consider the advisability of buying the cables of the Eastern Telegraph Companies, or of laying new cables to compete with those already in existence. In reply, the Chancellor of the Exchequer stated that Her Majesty's Government were not prepared to enter upon the wide question, involving, as it would, international negotiations, of buying up the cables of the Eastern Telegraph Companies, nor was it certain that their acquisition by the Government would lead to the desired results. But the Government would be glad if the labours of the International Telegraph Conference now sitting at Paris should have some result in the direction indicated in the question of the hon. member.

The British Association.—The programme for the Leeds meeting of the British Association has been issued. It commences on Wednesday, September 3, 1890. The president-elect is Sir Frederick Abel, F.R.S. The local secretaries for the meeting at Leeds are Mr. J. Rawlinson Ford, Mr. Sydney Lupton, Prof. L. C. Miall, and Prof. A. Smithells, and the local treasurer Mr. E. Beckett Faber. The presidents of the various sections are as follows:—A. Mathematical and physical science, Dr. J. W. L. Glaisher, D.Sc., F.R.S. B. Chemical science, Prof. T. E. Thorpe, B.Sc., F.R.S. C. Geology, Prof. A. H. Green, M.A., F.R.S. D. Biology, Prof. A. Milnes Marshall, D.Sc., F.R.S. E. Geography, Lieutenant-Colonel Sir R. Lambert Playfair, K.C.M.G. F. Economic science and statistics, Prof. Alfred Marshall, M.A. G. Mechanical science, Captain A. Noble, F.R.S. H. Anthropology, Mr. John Evans. The first general meeting will be held on Wednesday, September 3rd, at 8 p.m., when Prof. W. H. Flower will resign the chair, and Sir Frederick Abel, president-elect, will assume the presidency and deliver an address. On Thursday evening, September 4th, at 8 p.m., there will be a *soirée*; on Friday evening, September 5th, at 8:30 p.m., a discourse on "Mimicry," by Mr. E. B. Poulton, M.A., F.R.S.; on Monday evening, September 8th, at 8:30 p.m., a discourse on "Quartz Fibres and their Applications," by Prof. C. Vernon Boys, F.R.S.; on Tuesday evening, September 9th, at 8 p.m., a *soirée*; and on Wednesday, September 10th, the concluding general meeting will be held at 2:30 p.m.

Address to Sir James Anderson.—The following is the address presented to Sir James Anderson by the delegates assembled at Paris, on the occasion of his birthday on the 4th inst.:—

To Sir James Anderson.

We, the undersigned, attending the International Telegraph Conference in Paris, desire to take the opportunity of expressing to you our sincere and hearty congratulations on the occasion of your birthday and the fiftieth anniversary of the commencement of your first voyage—your jubilee of work and your golden wedding with the sea. We rejoice at your presence amongst us in the enjoyment of health and prosperity. We record our admiration of your long and successful career and high professional attainments as a sailor, and of the great services you have rendered in connection with the laying and repair of submarine telegraph cables in the deeper waters of the ocean. We wish also to express our warm appreciation of the ability and uprightness and unvarying courtesy and geniality which have distinguished your conduct of the business of the Telegraph Companies of which you have for many years been the Managing Director. We further congratulate you on the adoption by the present Conference of the project of an authorised International Vocabulary for telegraph messages, first proposed by you, and which you have for many years laboured to establish, believing, as we do, that this vocabulary will materially assist in securing the more speedy, accurate, and economical transmission of telegraphic communications in the future. With the assurance of our affectionate regard and high esteem, we wish you many years of continued usefulness and happiness.

John Pender, Thomas Fuller, C. W. Earle, A. J. Leppoc Cappel, William Ford, Charles Burt, W. Andrews, Alex. Wood, H. A. Mallock, Robt. Kaye Gray, Ernest Floyer, G. Von Chauvin, Jules Despêcher, R. T. Brown, Lewis Wells, Ch. Gerhardi, Wm. Payton, R. M. Cunningham, Jas. Scott, W. F. O'Brien, F. E. Hesse, G. Serpos, W. Hibberdine, P. Gatliff, T. A. Bullock, F. Moll, G. R. Neilson.

The County Council and Overhead Wires.—The Bill of the London County Council which asks the sanction of Parliament for powers to control overhead wires, came before a Select Committee of the House of Commons, under the presidency of Sir Joseph Bailey, on Wednesday. Mr. Pember, Q.C., addressed the Committee in favour of the scheme. The Bill, he said, was founded on a report made by a Committee to the House of Commons in the year 1885, which was appointed to consider the law in regard to telephone, telegraph, and other wires. That Committee came to the conclusion that the danger from overhead wires had been greatly exaggerated, and that accidents were few; but it was of opinion that, having regard to the increase of the telephonic system, it was desirable that a change in the law relating to the suspension of such wires should be made, but that it was not desirable that any course should be pursued which would hamper the extension of telephonic systems. Mr. Pember pointed out that if an alteration in the law was deemed necessary in 1885, it would necessarily be more so at the present time, owing to the great increase in the number of wires. Having read the Bill, he said he hoped he had proved to the Committee that it was in accord with the recommendations of the Committee of 1885; but if in any point it had gone beyond it, the five years that had elapsed had probably made that necessary. With regard to the opposition of the National Telephone Company, the Bill had been greatly modified in order to fall in with the views of that Company; but there were still points upon which they had not been able to agree, and if they were unable to do so before the conclusion of the inquiry, the Committee would have to decide the difference between them. The opposition of the Electric Supply Companies was passed over for the time to see whether an arrangement could not be arrived at. Mr. Pember then addressed the Committee on the opposition of the Corporation of London, which, he said, was desirous of retaining the control of all wires passing through the City. Evidence was then taken in support of counsel's statements.

ON THE PERMEABILITY OF IRON AT RIGHT ANGLES TO THE DIRECTION OF MAGNETISATION.

BY A. E. KENNELLY.

(*Concluded from page 114.*)

The theoretical relations existing between the inductances may now be considered.

Let a magnetising force, H, act upon a portion of homogeneous iron in the direction of x, a rectangular co-ordinate axis, and induce a magnetisation of amount I in the same direction, according to the relation $\mathsf{I} = f(\mathsf{H})$, then the induction per unit area $\mathsf{B} = \mathsf{H} + 4\pi f(\mathsf{H})$, and a closed solenoid surrounding a ring of this iron will, when measured with feeble currents, show an inductance L_x, expressed by the relation $L_x = l \frac{d\mathsf{B}}{d\mathsf{H}}$, l being the coil's inductance in a medium of unit permeability. Hence, the locus of L_x referred to H, should be a curve whose ordinates are proportional to $\frac{d\mathsf{B}}{d\mathsf{H}}$ at every point.

If, now, H receive a small increment, $d\mathsf{H}$, at right angles, or parallel to the y axis, then, provided that the iron is isotropic, the resultant magnetic force will lie in the plane $x\,y$, and make an angle, $\tan^{-1}\frac{d\mathsf{H}}{\mathsf{H}}$ with x. The component magnetisation, $\mathsf{I}\,y = \frac{d\mathsf{H}}{\mathsf{H}} f(\mathsf{H})$, the corresponding induction, $\mathsf{B}_y = d\mathsf{H} + 4\pi \frac{d\mathsf{H}}{\mathsf{H}} f(\mathsf{H})$, and the apparent inductance of the original solenoid, $L_y = l \frac{d\mathsf{B}_y}{d\mathsf{H}} = l\left\{1 + 4\pi \frac{f(\mathsf{H})}{\mathsf{H}}\right\} = l\mu$, where μ is the permeability of the iron in the direction x. The locus of L_y referred as before to H, will have its ordinates everywhere proportional to μ.

If, however, the iron is æolotropic, the magnetisation along y will be some function $\phi(\mathsf{H}, d\mathsf{H})$ of both H and $d\mathsf{H}$, so that any evident divergence between these two curves of L_y and μ, shown by experiment, marks the departure of the iron from the initial isotropic state in corresponding degree.

The results given in Tables III.—VI. are plotted in Figs. 2, 3, and 4. Examination of these curves shows:—

1st. That the curves of $L\,x$ do not indicate the very sudden rise in the value of $\frac{d\mathsf{B}}{d\mathsf{H}}$ known to take place within the first 10 units of H. This may, perhaps, be accounted for by supposing that at this stage the iron molecules are in a critical magnetic condition, and that the feeble magnetic force in the inductance test is insufficient to precipitate them.

2nd. That after H exceeds some 30 units, $L\,x$ appears in each case to be greater than $\frac{d\mathsf{B}}{d\mathsf{H}}$. This can only be attributed to error in the observation or method.

3rd. That in Figs. 3 and 4 the curves of $L\,y$ for values of H not less than 50 are rather more divergent from those of μ than $L\,x$ from $\frac{d\mathsf{B}}{d\mathsf{H}}$.

4th. That in Fig. 2, the case of wrought iron, there is a marked discrepancy between the two curves $L\,y$ and μ, the former being considerably in excess for magnetising forces above 20. The point of abrupt change of curvature in $L\,y$ appears to take place at a magnetising force of 9; and this, by a curious coincidence, is the value given by Mr. Shelford Bidwell for the "Villari critical point" in a particular instance.

While, therefore, the results with the rings of cast iron and tool-steel are doubtful, it may be safely inferred that the sample of wrought iron distinctly indicated æolotropic behaviour for magnetising forces exceeding 30 units; and this is not unreasonable when we remember that, according to Dr. Hopkinson, iron attains its maximum length at a magnetic force of 20. The contraction which sets in after that point may do such work against intermolecular forces as will by reaction affect the ratio $\frac{f(\mathsf{H})}{\mathsf{H}}$, or κ.

If this be admitted, Weber's theory cannot be regarded as theoretically correct for values of H exceeding 30, and beyond that point, at least, any strict theory of magnetisation must involve a consideration of molecular stresses and displacements.

Weber's theory, however great a stride over pre-existing conceptions, and however completely it enabled existing knowledge to cope mathematically with the intricate phenomena of magnetisation, is based upon what appears to be a very arbitrary hypothesis. It is assumed that the restituting force on the molecule varies directly with the sine of the displacement angle. The mechanism by which any such forces—magnetic or mechanical—could be exerted, unless as the result of some underlying hypothesis, is difficult to imagine. The amendments that Clerk-Maxwell introduced to enable it to cover the phenomena of hysteresis and permanent magnetisation, ingenious as they are, must also be confessed as very arbitrary. While his limitations of strain and "set" in the rotation of the molecules are, perhaps, the only ones capable of yielding a mathematical solution moderately simple, yet rationally complete, it tasks the imagination to suggest why just those particular limitations should naturally suggest themselves.

Moreover, the appearance in certain conditions of a stage of magnetic instability at which the ratio of magnetisation to magnetising force suddenly becomes discontinuously great, such a condition as has been observed by several physicists and lately pointed out by Professors Ewing and Thompson, cannot be accounted for by the Weber-Maxwell theory in its existing form, which only admits of continuous changes.

It is usually much easier to discover imperfections in existing theories, than to replace them by others less objectionable; but the following theory is offered as a suggestion. It is in reality only an adaptation of that promulgated by Prof. D. E. Hughes in his Papers to the Royal Society ten years since. In the following form, while embracing all those phenomena that Weber's theory explains, it has the advantage of explaining the stage of molecular instability, without being cumbered by special inherent limitations in the direction and magnitude of the restituting forces. At the same time it has the disadvantage of so attempting to portray the operations concerned in magnetisation, that a complete mathematical solution of the phases in transition is at present apparently beyond reach. It is also subject for its existence to the admission of an unusual postulate to be later specified. We may call it the "chain" theory of magnetisation.

Suppose the iron to be homogeneous, and to have n molecules per unit volume. As in Weber's theory, let the magnetic moment of each molecule be m, which varies only with the temperature. The maximum magnetisation possible is then

$$\mathsf{M} = n\,m.$$

In virgin iron under no magnetic influence, these molecules will be so arranged that there will be no resultant magnetisation. This we may suppose to result, not from any indiscriminate scattering of the magnetic axes in space, but from the formation under mutual attractive influences of closed loops or chains in the molecules. These chains may interlace in every conceivable manner, some may bifurcate or trifurcate in parts; but the characteristic feature of the magnetic arrangement in soft virgin iron will be the existence of magnetic chains made of two or more and usually many molecules as the rule, and the existence of unchained molecules isolated exceptions whose unstable condition renders them likely to fall into and form an offshoot loop of the nearest chain upon the slightest impulse. Let it also be granted that the seat of magnetic force is at the two extremities or poles of a magnetic axis connecting them fixed in the molecules and of length l, while the average distance d, intervening between the opposed poles of adjacent molecules in a chain is small compared with l. It may be remarked that this assumption is not equivalent to making the average intermolecular distance small compared with the dimensions of the molecule; for in the absence of knowledge concerning the nature of molecules, we are at liberty to place their poles in their "ether envelopes," or external it may be to their own proper space, provided that their poles are in rigid connection with them. The tendency of the magnetic

chains is to contract and reduce d, a tendency resisted by those forces which regulate the proportions and play of the molecular structure. This granted, it is easily seen that the magnetic moment of any one chain about any diameter as an axis will be small in relation to the moment of the molecule, while the chains being in all curvatures and azimuths, their aggregate moment in the mass must be vanishingly small.

Considering a single molecule in any chain, if r be the distance from one of the poles to any other pole in the mass, the magnetic force exerted between them will be a vector force ρ, expressed by the relation $\rho = m^2 f(r)$, where $f(r)$ may or may not be the function of inverse squares holding for sensible distances. Then the forces which are active in determining the direction of our selected molecule, assuming it to be free to turn on its centre in any direction, but to have the position of its centre prescribed by structural forces, will be two resultant magnetic forces, viz., $\Sigma \rho_p$ on the positive, and $\Sigma \rho_n$ on the negative pole, the summation being made vectorially and extended to every pole in the whole system. Since, however, d is small compared with l, the effect of the sphere of attractive force is practically confined to the nearest one or two molecules along the chain, while the influence of neighbouring molecules in other chains is a disturbing force generally small.

These two forces, $\Sigma \rho_p$ on p the positive pole, and $\Sigma \rho_n$ on n the negative pole, will be equivalent to a uniform magnetic field vectorially h say, acting on our molecule in the direction of its axis, and a single force, vectorially ϕ acting upon the molecular centre, tending to give it a motion of translations which tendency is presumed to be held in equilibrium by the mechanical forces of the molecular framework. This equivalent field h, and single central resultant ϕ, will exist for every molecule; and with reference to the chains, each h will be approximately tangent to the radius of curvature at that point, while ϕ will be directed towards the interior of the chain.

If now a vector magnetising force H be brought to bear upon the system, every molecule whose axis is not parallel to H will be magnetically deflected. Considering any single molecule, if its h remained constant, then its new axial position vectorially λ say in space would be in the resultant of h and H, or in line with the vector $\mathsf{H} + h$; but since nearly every molecule which previously contributed towards its h has also slightly deflected, the real new axial position will be in the vector line $\lambda = \mathsf{H} + (h - \Delta h)$, Δh representing the secondary disturbing effect on h.

The angle of deflection included between h and λ will vary for each molecule from zero for those originally in line with h to a maximum for those whose axes were originally nearest to a right angle with H. It is to be noticed that no matter what angle each chain might individually make with H, in parts or in planes, there will be always two and often more than two molecules opposite in each chain originally set so nearly perpendicular to H that their deflections in that chain are a maximum. Let us call these favoured molecules of a chain the "leaders."

Then if the chains were all composed of the same large number of molecules and similar in every respect, so arranged that however intimately they might be interlaced, no two chains ever approached within the sphere of mutual disturbing influence, the deflection of all the leaders would be equal, independent of the angle between their respective chain planes and H, for with all leaders h and H would be at right angles, h would have a common value, so also would Δh, and thus the deflection of each would be $\tan^{-1}\left(\frac{\mathsf{H}}{h - \Delta h}\right)$.

It may readily be granted that what would then be rigidly true for an ideally homogeneous system is nearly true by the theory of probabilities in a system partly subject to homogeneity, and partly left to fortuitous combinations, so that the

maximum deviation would be nearly alike in all chains and equal to the average value of $\tan^{-1}\left(\frac{H}{h-\Delta h}\right)$.

As H is now gradually increased all the deflections increase, but the increase is most rapid in the leaders, to which we may, therefore, confine our attention. If h were constant, the restituting moment due to h would increase with the angle of deflection; but owing to the secondary disturbance Δh, this moment does not increase in proportion to the moment of deflection due to H. This continues until h has been so much reduced by Δh, that a critical point is reached, and first reached in the leaders, when an increment in H, and therefore in the deflection, makes the restituting moment—just previously a maximum—diminish. At this stage nearly simultaneous with all the chains, the leaders break from their neighbours and rotate into parallelism with H. These neighbours, whose deflections had been next greatest in value, suddenly deprived of support, suffering a large increase in Δh, are precipitated into dislocation, and the example thus set is followed under transmitted influence all along the line till it terminates at the motionless molecules or nodal points originally parallel to H. The desertion of the leaders is thus the signal for the immediate disruption of the chains, which vanish without leaving a trace of their existence, and it may be that on the subsequent complete withdrawal of H, the associations, arrangement, and chains formed by the molecules under their once more ascendant mutual attractions may totally differ from those gone by.

If now elastic resistance to rotation be introduced as a factor, together with the stresses affecting the isotropic condition of the medium, the materials are present for suggesting every known description of paramagnetisation.

A few of the leading consequences of the theory may be outlined as follows:—

With a homogeneity of chain formation in marked degree, and very small resistance to rotation, the critical stage should be very pronounced, especially if the stresses produced by the magnetisation are either absent or removed by opposite imposed stresses. Such magnetisation would be almost entirely temporary, and there would be no coercive force. On first applying magnetic force, there would be a period of steadily increasing feeble magnetisation, then a sudden bound of almost complete magnetisation, followed by no subsequent change with any increase in magnetic force.

If, in the next instance, elastic resistance to rotation were introduced, the first stage of feeble magnetisation would not sensibly differ, and the critical stage would be reached at the same force, but the magnitude and duration of the bound would be modified in proportion to the resistance. The molecules would be retarded, and the chains might not instantly or coincidently break up on the departure of their leaders. Even after the disappearance of the chains, infinite magnetic force would be needed to produce in every molecule an indefinitely close convergence to parallelism, and the parallelism once produced would be more or less subpermanent.

Finally, as reaction stresses and want of chain homogenity are introduced, the critical stage in the magnetisation, although never entirely effaced, is more and more concealed, and the curve of $\frac{dB}{dH}$ shows a lower and less tapering apex.

Between these limits, all the characteristics of magnetised iron seem to be included.

As regards the stresses produced in iron by the process of magnetisation, we should expect to discover a voluminal expansion up to the critical stage owing to the reduction of the ϕ forces, which in the virgin state are directed towards the chain centres as already noticed. Once the critical stage is reached, however, there should be a linear shrinkage in the direction of H, accompanied probably by an expansion in all directions at right angles, owing to the mutual attraction of all the consecutive polarised molecules. This shrinkage should be instantaneous and final in ideally soft and homogeneous iron, while it would be gradually affected to an equal limiting amount in iron subject to elastic resistance.

This deduction appears to agree fairly with the observed facts, so far as they are recorded for iron, but the anomalous behaviour of cobalt and nickel in this respect has yet to be accounted for; and in fact, as Dr. Hopkinson pointed out in his able address to the London Institute of Electrical Engineers this year, no theory of magnetisation can ever be considered complete until the origin and phenomena of molecular polarity, the essence of the whole subject, are satisfactorily explained.

THE WESTINGHOUSE CONSTANT-CURRENT ALTERNATING SYSTEM.

By constant current in this connection it will be understood that the value of the alternating current as measured by a dynamometer, or the square root of the mean square of the periodic current, is a constant quantity.

In *The Electrician* of April 25th a description of the new Westinghouse arc light system was reproduced from the *Electrical Engineer* of New York, with some illustrations showing the general appearance and construction of the armature of the generator; also a table and curves of efficiencies attained. The additional information with regard to this system contained in the following notes may, however, prove of practical interest.

The objects which the Westinghouse Company had in view in this system were—first, to enable them to build larger machines for arc lighting (and thus increase the size of the plant unit) without unduly increasing the potential of the current; and, secondly, to enable them to insulate the lamps themselves from the high-tension mains. It is evident that a constant-current system must necessarily be a series system, if there is to be any variation in the load; and the present system is one in which the converters are connected in series with the line. Constant current in the primary of a converter means that if the windings are as 1 to 1 the current in the

Fig. 1.—10-Ampere Circuit.

secondary is absolutely limited to a value a little below that of the primary current; or, if the windings are as 1 to 3, for instance, then the current in the secondary is limited to slightly less than one-third the primary current. This limitation of the strength of current, combined, as it necessarily is, with a very rapid rise of volts in the secondary if the current falls in consequence of an increase of resistance in the secondary circuit, is precisely what is wanted to ensure stability and consequent absence of flickering in arc lighting resistance coils such as are required in all cases when arc lamps are run on constant potential circuits being of course dispensed with. The system is intended more especially for street lighting; but in America private users are also supplied by it When the number of lamps required on a single circuit does not exceed 60, a current of 10 amperes is employed, in which case the converters can be dispensed with altogether in the case of street lamps, if no objection is made to their being in connection with the high-tension mains. In American towns and cities, where this system has been adopted, private users have also been allowed to have lamps supplied direct without the use of converters if they wish to avoid the cost of the converter, and accept the risk as regards the high tension.

Fig. 1 is a diagram of a 10-ampere circuit. A A A represents private consumer's lamps supplied with the use of converters. B B represents private consumers who accept the risk of the high-tension mains coming into their premises. C C represents street lamps with converters, and D D street lamps connected directly in series with high-tension mains. The larger machines at present constructed have capacities of 120 and 240 lights respectively, and employ a current of 30 amperes, the larger of the two machines having two independent circuits. This

Digitized by Google

current is much too large for street lamps, so that the facility of connecting lamps directly in series with the mains is practically lost in the case of the larger machines.

Fig. 2 is a diagram of a 30-ampere circuit. A represents two lights, B one light, and C three lights, run from converters for private consumers. E E E represents street lamps also run from converters.

The exciting magnets, and also the external appearance of the constant-current machines, are similar to those of the Westinghouse constant potential alternators, the difference being in the construction of the armature (see *The Electrician*, April 25th), which is provided with large overlapping teeth, slightly wider than the gaps between the field poles, so that

Fig. 2.—30-Ampere Circuit.

the edge of one tooth comes under a magnet pole just before another has entirely left. The teeth are equal in number to the field poles, and each tooth carries a constituent coil of the armature winding. No regulating apparatus whatever is employed to keep the current constant, the machine being so designed that the magnetic flux through the armature, and consequently the E.M.F. generated, is practically proportional to the resistance in circuit. Although the action of the machine is well described in the latter part of the reprint referred to above, the following description, with the aid of the sketches Figs. 3, 4 and 5, may give a clearer insight into the way in which self-regulation is secured. The proportion of the winding of the armature to that of the field coils is such that at the moment of maximum current the ampere turns of the armature coils are approximately equal to those of the field coils, and consequently if the armature current reaches its maximum at a moment when the teeth approach coincidence with the poles the magnetic flux will be very small and the E.M.F. generated only just sufficient to send a harmless current through the armature when short-circuited. In Fig. 3 the

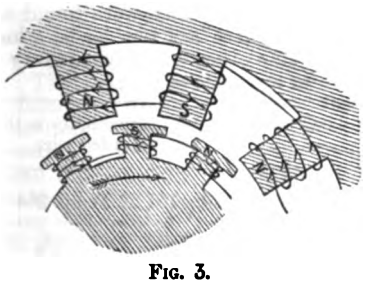

Fig. 3.

armature teeth are shown in the position midway between the field poles, and, as is well understood, the induced E.M.F. will be at a maximum in this position. If no current is allowed to flow, the field coils produce a large magnetic flux, and a high E.M.F. is generated which in the machines as constructed may reach 10,000 volts or so. It is therefore advisable for safety to short-circuit the armature when running without load, and an automatic arrangement is provided on each machine to effect this. If, now, the armature circuit is closed with a moderate resistance in circuit the lagging of the current behind the impressed E.M.F. causes the armature teeth to have made an approach towards coincidence with the magnet poles (*see* Fig. 4) at the time when the current in the armature coils has reached its maximum value. This approach towards coincidence considerably increases the self-induction of the armature by improving the magnetic circuit, which has the effect of making the lag much greater than it would have been had the self-induction of the armature remained constant; so that by a cumulative process the lag due to an increase of current in the armature winding is considerably magnified. The approach towards coincidence between the armature teeth and the magnet coils at the moment of maximum current also has the effect of directly cutting down the E.M.F. by bringing the magnetising force of the armature winding into more direct opposition with that of the field coils, and thus reducing the magnetic flux through the armature, until when coincidence is practically reached (see Fig. 5)—as it is when the armature is short-circuited—the armature and field windings oppose each other on very nearly equal terms, and the magnetic flux is only sufficient to cause a slightly increased current in the armature. In the machines as constructed, if the resistance inserted consists of a load of converters in series, with arc lamps in their

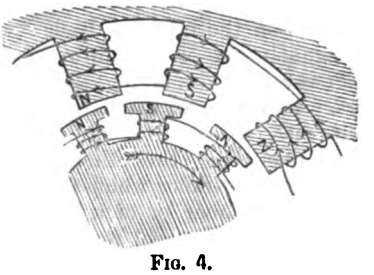

Fig. 4.

secondaries, the lag due to the current flowing in the armature will be such that the magnetic flux due to the resultant of the magnetising forces of the field and armature coils will be of the value necessary to produce the normal volts for that particular load, and the Westinghouse Company claim to have succeeded in turning out machines so sensitive that a practically negligible variation in the current causes a variation of E.M.F. in the external circuit from nil when the armature is short-circuited up to 2,000 or 3,000 volts when loaded up with converters and arc lamps. It is stated that the full load can be suddenly thrown on or off without doing any damage to the machine, the current remaining practically steady during either operation. The 240 light machines, as has already been stated, are two circuit machines, and are generally employed in large towns and cities for street lighting, where there is not much variation in the load, when it is found that the interference between the two circuits is not noticeable. It is, of course, impossible that the two circuits should regulate independently.

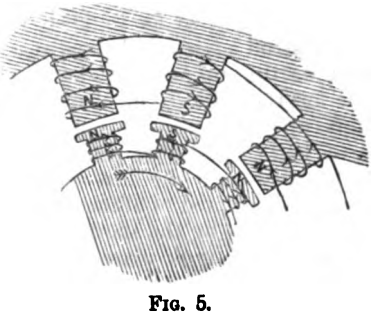

Fig. 5.

The transformer employed is a closed circuit one. Lamps are extinguished by short-circuiting the *secondary* coil, a proceeding which causes very little waste of energy, owing to the low value reached by the induction in the iron and the small resistance of the copper circuit. The results of the secondary being on open circuit would be to cause heating of the core, due to the high value reached by the induction, and to choke the primary. To insure perfect insulation between the primary and secondary coils, they are wound on separate bobbins, with a considerable space between the two. The slight loss of efficiency resulting from this arrangement is said to be of little importance in a series arc system. The space between the coils and the cover is filled up with wood blocks and insulating compound, the object of the latter being to keep out damp; the practice is one which we think will hardly be regarded with favour by English electricians.

With regard to the arc lamp, the only new point which has not been already described in these pages is the addition of a small reflector around the upper carbon to throw the rays from the lower carbon crater in a useful direction.

THE STORAGE CELLS AT THE CHELSEA ELECTRICITY SUPPLY COMPANY'S SUB-STATIONS.

In the article on the above Company's station and sub-stations which appeared in our issue of May 30 we confined ourselves to a general description of the plant and working arrangements. We now give some particulars of the method adopted of mounting and starting the storage cells, and of their present condition.

Those who have had to do with storage cells are sufficiently familiar with the difficulties of handling them; and any practical person can get a fair idea of these difficulties by picturing to himself a glass box on the top of a high shelf, full to the brim with a strong solution of sulphuric acid, in which is immersed about 2cwt. of lead plates. Added to this is the fact that the storage battery man has to deal not with one cell standing by itself with space all around it, but with tiers of shelves arranged one above the other, on which cells are packed with the smallest clearance which safety considerations will allow. A slip of a spanner, or of a ladder, or of the suspension hook of the traveller, might result in the shelves and connections beneath being deluged with 10 per cent. solution of sulphuric acid. It will be seen, then, that the overhauling of a cell is a matter requiring time and care for its execution; and the fact, stated by the Company's engineer, that two men have been found sufficient to do all that has been necessary for three sub-stations, having an aggregate of 1,365 cells, is *primâ facie* evidence that up to the present the amount of attention required by the cells is not great.

The cells are supported by upright frames of cast-iron, between which are fixed wooden bearers of a length sufficient to take, in some cases three, and in others four cells in a row. The ironwork is served with three good coats of red paint, and the wooden bearers with an equal number of coats of shellac varnish, while the spaces between the ends of the bearers and the ironwork are filled up with a mixture of bitumen and tar, with the object of preventing spilled acid or the spray which is caused by the breaking of the gas bubbles from getting between and causing destruction of wood and iron alike. Each cell stands upon a wooden tray filled with sawdust, which is supported by four Johnson and Phillips oil insulators, which rest upon the wood bearers above described. As far as is practicable, the cells are arranged so as to keep the difference of potential between those on adjacent shelves at a low value.

The time of first starting up a storage battery is well known to be a critical one for the cells. The charging ought to commence immediately after the acid is poured in; but as this process of filling a large number of cells necessarily occupies several hours, in practice only the last cells filled have this advantage. The method adopted of filling up the large number of cells at each sub-station in the shortest possible time has been to provide a lead-lined tank above the level of the cells into which the acid is poured direct from the carboys. An india-rubber hose is connected to the tank, by means of which the cells are filled in rapid succession. The filling of the cells at Clabon Mews occupied about six hours, after which charging was continued for upwards of thirty hours without cessation. This battery has now been in constant use for fifteen months, and at the time of our visit had the appearance of being in good order; nor were any of the well-known signs visible—in the shape of bent lugs or other unavoidable marks—of cells having been taken out and overhauled. The negative plates were scaling to some extent, and we noticed some positive plates which appeared to have lost some of the paste from the surfaces of the squares; but the space which is now provided at the bottom of the cells prevents the falling scale from giving trouble by shortcircuiting. We saw no signs whatever of buckling of the plates; and the opinion we formed after a close and careful inspection was that the battery was in thoroughly good working order. It may be mentioned that the back E.M.F. cells are generally made up with grids only, pasted plates being put into a sufficient number of cells to supply the current required for the various automatic apparatus.

Our account of this Company's station would be incomplete without mention of the name of Mr. Frank King in connection with the inception of the system and the ingenious automatic devices which distinguish this Company's system of supply from any other at present in operation. The fact that these devices have now been working without a hitch for several months must be highly satisfactory to him as the person responsible for their design and manufacture, especially when we remember the doubts expressed by many at the time when Major-General Webber described the arrangements at the British Association last year as to the possibility of a system which appeared so complex on paper proving successful in practice. The whole of the batteries and the automatic accessories were, we may add, manufactured and supplied by the old E. P. S. Company; and the extensions now in progress are being carried out, under Mr. King's supervision, by the successors of the E. P. S. Company, the Electric Construction Corporation, who are the owners of the patents in connection with this system.

THE PHYSICAL SOCIETY.

At the meeting of this Society held on the 6th inst., Mr. H. TOMLINSON read a Paper

"On the Effect of Change of Temperature on the Villari Critical Point of Iron"

The author observed that as in his former Paper (see *The Electrician*, April 4, 1890, p. 547), the temporary magnetisation only was considered, and the method of observation was the same as previously described; but he had now examined the effect of loading at various temperatures, extending up to 285° C. The temperature was determined by means of a coil of platinum wire wound double over the same part of the iron as the secondary coil, the temperature coefficient of this platinum coil having been previously determined. The iron wire, one millimetre in diameter, was thoroughly annealed, and the loads employed were not sufficient to produce any sensible permanent extension.

In the first instance the wire was heated to 300° C., and tested at the various load and magnetising forces at this temperature, and again after cooling to the temperature of the room, and this was repeated several times until constant results were obtained. The results of the observations were plotted as curves, the abscissæ of which represented the load in kilogrammes, while the ordinates represented the percentage alteration in permeability. The Villari critical point, or the value of the magnetising force for which loading does not affect the permeability, was given by the point of intersection of each curve with the load-line, and it was found to vary both with the load and the temperature. In some cases the curves which were exhibited to the Society were found to cut the load-line twice, showing that there are two loads, which, for certain magnetising forces, have no effect on the temporary magnetisation. These loads are given in the table below :—

—	Load for which the permeability is the same as for the unloaded wire.			
Magnetizing force in C.G.S. units.	Temp. 76° C.	Temp. 167° C.	Temp. 244° C.	Temp. 285° C.
2·84	5·0	5·3 12·0	5·7 10·0	
3·70	3·2	3·6	4·2 11·5	4·7 9·9
4·83	2·5	2·7	Not tested.	3·1 12·3

It follows, therefore, that all magnetising forces between 2·84 and 4·83 are Villari critical values. Regarding only the first point at which each curve intersected the line of loads, the observations showed that, at all temperatures, the Villari critical value increases as the load decreases, and for a given load increases with the temperature. Considering also the second point of intersection, they show that the Villari critical value increases both with the load and with the temperature, so that the effect of change of temperature on the critical value is in the same direction for both points of intersection, and therefore in both cases the critical value increases with the temperature. The curve showed that as the temperature increases the two points of intersection with the load-line gradually approach each other, until, at a temperature a little below 285° C., they coincide, and the curve osculates the load-line, while at higher temperatures than this the magnetising force 2·84 ceases to be a Villari point for any load. When the magnetising force attains the value 7·69 both points of intersection vanish, for loads up to 12 kilogrammes, though the second point would probably be obtained by taking

Digitized by Google

sufficiently high loads. Below this limit, therefore, as regards the load, Villari points are impossible for magnetising forces beyond 7·69. Rise of temperature was found invariably to increase the change of permeability in the positive direction, and to diminish it in the negative direction ; but the diminution was greater than the increment, so that the two bends in the curves tended to approach the same level.

The percentage alteration of permeability was calculated in the following manner. Let P_o be the temporary permeability when unloaded, and P_n the permeability with a load of n kilogrammes, then the percentage alteration is—

$$\pm\frac{100\,(P_n - P_o)}{P_o},$$

the upper sign indicating that loading increases the permeability, and the lower one that it decreases it. The table below gives the values of P_o for the various temperatures and magnetising forces at which the observations were made.

Magnetising force in C.G.S. units.	Values of P_o.				
	12° C.	76° C.	167° C.	244° C.	285° C.

A Paper, by Messrs. W. G. Robson and S. W. J. Smith,

"On the Diurnal Variations of the Magnet at Kew,"

was then read.

The authors considered that the multiplication of magnetic observations made it highly desirable that the methods of reducing the observations should be as similar as possible. It was, however, practically impossible for all observatories to determine the diurnal variations of the elements by the elaborate method in use at Greenwich, which for any one element necessitated the measurement of the hourly ordinates of the curves at 24 points on all but a very few days of the year under consideration. Dr. Wild (British Association Report, 1885, p. 78) advocated the determination of the mean diurnal range from measurements made on the comparatively few days of very small disturbance, and pointed out that the inclusion of disturbed days would affect the form of the curve of diurnal range unless the disturbances occurred indifferently at all hours of the twenty-four. Mr. Whipple had compared the method in use at Greenwich with those of Wild and Sabine for the years 1870, 1871, and 1872 (British Association Report, 1886, p. 71), and came to the conclusion that the difference between the Kew results, as treated by the methods of Wild and Sabine respectively, was less than the difference between the Greenwich and Kew results in either case. The authors decided to make some further comparison of the different methods of reduction, and at Prof. Rücker's request they determined the diurnal variation of the declination at Kew for the years 1883 (a year of maximum sun spots), 1886, and 1887. The mean diurnal range during each year was obtained by Wild's method, the hourly ordinates for about five quiet days in each month being measured. The results obtained were then compared with the corresponding published Greenwich results. The total ranges in each year, according to the two series of observations, are given below :—

Total Ranges.

Year.	Kew.	Greenwich.
1883.	9′·0	8′·5
1886.	7′·6	7′·3
1887.	7′·4	6′·9

The authors point out as noteworthy that the total range at Kew, determined from quiet days only, is greater than that at Greenwich, determined from all days except those of great disturbance. This would appear to indicate that the effect of magnetic storms is to diminish and not to increase the diurnal excursions of the needle. The range of differences of the corresponding mean hourly values is given below :—

——	Range of Differences.	Year.
Greenwich—Kew	−0′·7 to +0′·8	1883
,, ,,	−1′·1 to +0′·7	1886
,, ,,	−1′·1$_4$ to +0′·8	1887

A comparison of this table with the preceding one gives for the percentage differences in the ranges, 16·7, 23·7, and 25·7 respectively. A comparison of the differences of the hourly readings for these three years with those given by Mr. Whipple for the years 1870-72 shows that there is a considerable uniformity in the nature of the differences between the mean hourly readings for Greenwich and Kew respectively. Thus, in each year, the Greenwich mean curve was found to fall below that obtained from the Kew magnetograph at about 7 p.m., and to remain below it until about 4 a.m., after which it remained above the Kew curve until it crossed it about 7 p.m. The minimum ordinate for each curve in each year was found to occur at about 8 a.m., and the maximum ordinate at 1 p.m. The mean value of the declination occurred between 10 a.m. and 11 a.m., and again between 6 p.m. and 7 p.m. Exactly similar features occur in Mr. Whipple's tables for the years 1870-72, and therefore the authors consider that it may fairly be assumed that the general nature of the difference between the Greenwich and Kew mean curves from 1870 to 1887 is the same. The individual readings do not differ from the corresponding mean to an extent greater than 0′·4 ; and they infer that it would be possible, knowing one set of values for any particular year, Greenwich or Kew, to determine the other set, correct to within four-tenths of a minute. As the Kew results are published earlier than the Greenwich ones, the latter might be calculated approximately from the former.

DISCUSSION.

Mr. WHIPPLE said the question as to the manner in which a magnet moves over a few minutes of arc might not seem of much importance, but the fact remained that physicists had always taken great interest in these movements. Before recording instruments were available the numbers had to be obtained by separate experiments. The labour involved in this was considerable, and a single large disturbance might vitiate a whole year's work. Methods of eliminating these disturbances were therefore adopted, amongst which that employed by Sabine might be particularly mentioned. The reason, he thought, why attention had been chiefly directed to declination was because of the relative ease with which such observations could be obtained and reduced. Now that such results had been recorded, it remained to find the causes of the observed variations. These changes did not seem to depend on temperature or on astronomical facts. He said it was very important to obtain magnetic results from different parts of the world ; but comparisons were only possible when all the observations were published on the same plan. He hoped this desideratum would be brought about as the result of the efforts of Professors Rücker and Adams. As soon as this was accomplished the observations on Force would have to be considered. This work would be very laborious, and therefore the aid of volunteers, such as the authors of the Paper just read, would greatly accelerate progress.

Prof. W. G. ADAMS observed that he was glad to see the satisfactory nature of the work which had just been brought before the Society. Usually the mass of figures to be dealt with was so large that the mere reduction was a great undertaking. If, however, the differences between the Greenwich and Wild's methods was not more than $\frac{4}{10}$ths of a minute, the latter might be used with advantage, and might possibly lead to the discovery of the cause of the diurnal variations.

The PRESIDENT (Prof. Ayrton) observed that the movement initiated by Prof. Rücker would be of great value if it resulted in the records of all observatories being published in the same way. It was a great advantage to science that such men as he (Prof. Rücker), who were not permanently attached to any observatory, should take up the subject and suggest improvements ; for the heads of such institutions were usually kept too fully employed in making the necessary reductions, to have time to consider and devise improved methods. In his opinion greater freedom should be granted to the chiefs of such observatories, for it must be borne in mind that the object of the observations was not to produce volumes of figures, but to increase knowledge. Referring to the reduction of observations, he expressed it as his opinion that the voluntary services of senior physical students should be more generally accepted, and to this end he suggested that properly recommended students should be permitted to spend some time in observatories as honorary assistants. This would be a great assistance to the students themselves, and would also enable the reductions to be expedited.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, June 13th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Physical Foundation of Music." By Prof. SILVANUS P. THOMPSON, D.Sc.

MONDAY, June 16th.

LONDON CHAMBER OF COMMERCE.

2:30 p.m. Electrical Trades Section. Committee Meeting at Botolph House, Eastcheap.

FRIDAY, June 20th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: "The Stretching of Liquids." By Prof. A. W. WORTHINGTON. "The Measurement of Electro-Magnetic Radiation." By C. V. BOYS, A. E. BRISCOE and W. WATSON. "Notes on Secondary Batteries." By Dr. GLADSTONE and W. HIBBERT.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

THE INSTITUTION OF ELECTRICAL ENGINEERS' VISIT TO EDINBURGH.

Our New York letter last week contained an interesting account of the doings of the American Institute of Electrical Engineers, which has been holding its meetings away from headquarters somewhat on the lines of our own British Association gatherings. This was not the first time the experiment had been tried on the other side the Atlantic, but the recent meeting seems to have been exceptionally successful, and promoted as it was by the representatives of American electrical industry is of especial interest to our readers. On Tuesday, 20th May, the usual annual meeting was held in New York, when, after the business of electing officers for the ensuing year was completed, the members listened to a Paper on "Electricity in the Navy"; and then, so many of them as could get away, proceeded by night train to Boston, at which place, on the following day, the meeting was continued, and a number of valuable Papers were read and discussed. For the Boston part of the proceedings the Massachusetts

Digitized by Google

Institute of Technology opened its doors, affording substantial hospitality in the evening; and on the day following visits were paid to all the more important electrical companies' works in the city and neighbourhood. Altogether the outing was so great a success that invitations to visit other great centres of industry or of scientific learning will probably not long be wanting.

For the purpose of creating local interest in the objects of such societies, as well as for strengthening the community of interests which attach them to the scattered members of the profession they represent, no more useful or sensible plan could be devised than this of extending the meetings beyond the narrow boundaries of the central meeting-house. We are glad, therefore, to notice the experiment of this kind that is about to be tried by the Institution of Electrical Engineers, whose headquarters are, not in New York, but at Westminster, and this in connection with the Electrical Exhibition now being held in the northern capital. The meeting of the London society in Edinburgh has been announced for the 15th, 16th, and 17th of July; and it is very possible that, if this early date is adhered to, the result may be a somewhat meagre attendance. However that may be, the place and the occasion are admirably chosen, and with ordinary care the result ought to be satisfactory as well to the guests as to their entertainers.

Although it has changed its programme to some extent, the Exhibition is still conspicuously an electrical one; and there is a peculiar appropriateness in this state visit of the chief electrical society of Great Britain to an enterprise of that kind. Moreover, Scotland contributes very powerfully to the scientific side of electrical industry, and, with a little encouragement, promises to become a valuable field for its practical application. Metropolitan members of the Institution, if they have much to tell their northern friends, will have also much to hear that will be useful to bring away with them.

The programme of the visit is, of course, not yet made known; but we understand that numerous Papers will be read, more especially such as relate to the electrical features of the Exhibition itself, one by Prof. Ayrton on "Accumulators." The Council will be entertained by the Exhibition Committee; and, as usual at these times, various excursions will be organised for the pleasure and profit of the members. In this connection we naturally recall the liberality of the railway companies, to say nothing of the Exhibition Committee, on the occasion of the opening ceremony. Our American cousins do not hesitate to hire an electrical special train—that is to say, not a train motered by electricity, but carrying passengers belonging to the electrical profession exclusively. It is a sensational notion, and is, of course, designed to create the sensation intended. Our British dignity may not stoop to this kind of advertisement; but it need not be ashamed to approach the railway companies for the purpose of cheapening the journey and extending it to those places of interest with which Scotland so largely abounds. The ordinary express fares are very high, and to a great many members of the Institution are prohibitive. It would contribute not a little to the *prestige* of the gathering if the expense could be so far lessened as to tempt a very large number of the English members to join the party. If they mustered in any considerable force it might pay the railway company even to run an "electrical special" for their benefit.

One other practical suggestion we would venture to offer in connection with the meetings at Edinburgh, namely, that the Council should relax for the occasion their rule against reporters from the technical press. We have mentioned that reunions of this kind always evoke a good deal of local interest, as is right and desirable they should. Representatives of the local press are not merely admitted, but every encouragement is given for the publication of reports of the proceedings from day to day. This is invariably the case during meetings of the British Association; and to some extent, no doubt, the same course will be followed at the Edinburgh meetings of the Institution of Electrical Engineers. Under these circumstances, it would be extremely unfair to deny to the London technical journals what will be freely given to the newspapers of Edinburgh and Glasgow. On occasions like these the Institution must necessarily throw off its reserve in coming before the public at large; and it would be very ill-advised to curtail the facilities for reporting in the only journals that will care to do it full justice.

REVIEWS.

Gas and Petroleum Engines: a Practical Treatise on the Internal Combustion Engine. By William Robinson, M.E. (London: E. and F. N. Spon.)

Engineers who have experience in working steam engines as well as gas engines, no doubt prefer the former to the latter. The steam engine is always ready to start without requiring the waste of a great deal of bodily energy in turning the fly-wheel; it is noiseless, does not smell, easy to put right if anything goes wrong, and, what is most important, it is well understood. The gas engine is a terrible nuisance as a next-door neighbour; it is very often difficult to start, and it often stops without warning; but still all these faults may generally be attributed to the fact that it is not properly understood. The steam engine requires a boiler, and this is very inconvenient for small powers, and at places where space is not abundant; it requires an attendant to be always on the spot to see that the pressure is right, and that there is water enough in the boiler, &c. The gas engine does not require continuous attendance, it only wants a proper-sized meter and feed-pipe and exhaust-pipe. What would electrical engineers have done in many cases if there had been no gas engine?

For these reasons we ought to welcome a book, of which the object is to aid students and practical men in studying this class of engines. The present book is written with this intention, and not only treats on the gas engine, but on the internal combustion engine in general. It begins with the action of the Otto gas engine, which is fully described in detail, with indicator-diagrams, and instructions for starting and working the engine; then follow the Atkinson engine and Powell's Simplex engine, with good explanatory diagrams, and the results of trials. The next chapter deals with petroleum as used in prime motors. This new engine has the advantage of not requiring the presence of gas works, and is well worth the attention of engineers, who will find a good description of the Priestman and Spiel's engines in this book. After explaining the working of Messrs. Yarrow and Co.'s spirit launch, and the "Bailey-Friedrich" petroleum steam motor, there follows a chapter on the history of combustion and caloric engines, which gives interesting and useful information with regard to the development of these engines. In the following chapters the classification of internal combustion engines, mechanism for ignition, admission, and governing, as used in the various modern engines, are all very fully described, with sufficient diagrams.

It is the custom in all text-books dealing with any branch of engineering, to give an account of mass, force and mechanical units as used in practice, the object being to clear away dark clouds from the mind of the reader, who very seldom perfectly understands the foundations upon which mechanics are based. In most text-books this is done in a way which, instead of enlightening the mind of the reader, brings him still further away from the point; and we are sorry to say that this is also the case in some instances in this book in which the engineering units of force and mass are not at all well defined. The

Digitized by Google

chapters on heat, including the theory of gases, calorimetry, thermometry, combustion, and fuel, are all very clear and complete, and their presence in a book of this kind is correct. Then comes $\frac{T_2 - T_1}{T_2}$ representing the efficiency of an imaginary engine worked by imaginary gases, and applied to real engines worked by real gases. This subject is certainly treated in a much better way than is usually the case in text-books. The book winds up with a chapter on a series of trials with gas-engines, which are all instructive, and well worth studying.

This book, it may be said, gives the fullest record of the internal combustion engine yet published, and is on the whole clear and instructive; and we can congratulate the author on the result of his labour.

LIFE AND EFFICIENCY OF ARC-LIGHT CARBONS.*

BY LOUIS B. MARKS, M.E.

It was with a view of studying the action of modern carbon pencils that the investigations here to be described were undertaken. The carbons experimented upon were all of American manufacture, and were procured from five companies (A, B, C, D and E). While the greater part of the research was upon the life and efficiency of the pencils, observations were also made in other directions.

The subject will be treated under the following heads:—

1st. Structure of the carbons.
2nd. Life tests.
3rd. Efficiencies.
4th. Candle-power measurements.
5th. Observations of the arc and carbon points.

It is well known that the life and efficiency of a carbon depends upon the system in which the latter is burned. For instance, "the requirement of the low-tension system seems to be a carbon that is hard, well plated, and a good conductor, the latter being the most important." "In the high-tension system, on the contrary, hardness and conductivity seem to be of secondary importance. There is a tendency to 'flame' and burn unsteadily when a hard carbon is used in this system, and a softer one sometimes becomes necessary."† It is interesting to note the methods employed by carbon manufacturers to attain the conditions above mentioned. In one of our largest carbon works "forced" carbons, or those made by "squirting" the plastic material through a die, are manufactured for both high and low tension systems of lighting, to the exclusion of moulded pencils. On the other hand, another company makes no forced carbons, but claims that its moulded pencils are superior for either system. From the classification given below can be seen the types of carbons now upon the market for both systems.

One of the first things that suggested itself was the study of the structure of the various samples submitted. For this purpose thin transverse sections of all the specimens were cut and mounted on glass slides, and a microscopical examination made.

There is a marked difference between the structure of a moulded and a forced carbon. In the high-tension pencil of the brand A, for instance, the structure is a loose one, while the low-tension rod of the same group is marked by a dense homogeneous structure; the size of the grains of carbon in the latter case is very much less than in the former, and, as seen under the magnifying power of the microscope, the particles have a more metalloid lustre. Again, there is probably considerable air-space in Fig. 1.

Life Tests.

If a carbon is burned with a small current its life will be long at a sacrifice of light-giving properties. If, on the other hand, a large current is used, there may be a gain in efficiency at a sacrifice of life. The question arises—what is the proper current to use? Of course, circumstances determine to a large extent the answer, and generally such a current is used as gives a fair mortality at a reasonable efficiency of the carbon. The high-tension carbons submitted for test were designed to be burned at about 10 amperes, and the low tension at about 20. In the life tests a Thomson lamp was used for high-tension runs, current being kept constant at 10 amperes and potential difference at 50 volts. For low-tension carbons the Weston lamp was used. The pencils were accurately weighed before and after the runs, and the life calculated on the assumption that the carbons were homogeneous. Each set of pencils was burned an hour. The results of tests are given in Table 1.

Table I.—*Life Tests.*

Carbon.	Mean diam. Inches.	Resistance. Ohms.	Initial wt. + grms.	Initial wt. - grms.	C. amperes.	P. D. volts.	Loss in wt. + grms.	Loss in wt. - grms.	Life 12in+carbon hours.

E. Moulded high tension*	·533	·202	63·30	30·48	10·	50	6·09	3·04	10·39
E. Forced low tension* ..	·522	·251	59·62	29·81	10·	50	5·91	3·52	10·09

* Naked. † Plated.

‡ These low-tension runs were made with the Weston plant on the University Campus. Ten lamps were run in series. Time of test was 2½ hours in the case of carbons B and E, and 2 hours and 25 minutes in the case of C.

It has been stated that "with carbons of the same *hardness* and length but having different diameters, the larger will undoubtedly outlive the smaller. Of carbons of the same *diameter* and length, but differing in hardness, the harder will outlive the softer."* This statement presupposes that the conductivity of the carbon is directly dependant on the hardness or softness of the pencil. In order to examine more fully the relation between diameter, resistance and mortality of a pencil, six sets of carbons of the brand B, varying in diameter from ½ to 1½ inch, were carefully weighed, their resistances measured by the Wheatstone bridge method, and the pencils burned with a constant current of 10 amperes from a Gramme dynamo, the potential difference at the terminals of the lamp being kept at 50 volts. The diameters and resistances respectively of the upper and lower carbons were in each case practically the same. A mean of 10 micrometer measurements of the diameter was taken as correct. The duration of each run was 60 minutes.

Following are the data:—

Table II.—*Mortality with Different Diameters.*

Carbon.	Mean diameter. Inches.	Resistance. Ohms.	Initial wt. + grms.	Loss wt. + grms.	Life 12in. + carbon hours.
B. Moulded high tension..	·453	·0805	44·70	4·20	10·64
" " ...	·505	·075	58·17	4·80	12·12
" " ...	·618	·0735	94·93	6·96	13·64
" " ...	·739	·0615	132·34	6·19	21·38
" " ...	·986	·061	232·20	8·88	26·15
" " ...	1·195	·059	339·57	10·14	33·49

From the results given in Table II., it appears that the life of a carbon varies *directly* with its *diameter* and *inversely* with its *resistance*. This law holds only for homogeneous carbons of the same manufacture, type and structure, and, as stated before, for constant current and voltage.

Let us take the ½in. (·505in.) and 1in. (·986in.) pencils as standards, and, from the relation above stated, calculate the mortality of the other carbons. Table III., gives a comparison of the actual and the calculated life of the various specimens tested.

Table III.

Carbon.	Mean diameter. Inches.	Standard ½ in. (·505 in.) Calculated life hours.	Standard 1 in. (·986 in.) Calculated life hours.	Actual life hours.
B. Moulded light.....	·453	10·92	9·32	10·64
" "	·618	15·10	13·62	13·64
" "	·739	21·58	19·44	21·38
" "	1·195	36·40	33·04	33·39

Thus it appears that the calculated life throughout the series is larger than the actual when the ½ in. carbon is taken as a standard and smaller when the 1 in. pencil is made the basis of calculation.

The carbons of group B were not perfectly round, a variation of 3% being at times found, between the 10 measurements of the diameter of a pencil. In determining the resistance of the carbon rods, the tips of the latter were copper-plated when necessary and mercurial contacts used. The lamp was adjusted to burn at 50 volts potential difference for each set of pencils. While every pre-

caution was taken to avoid discrepancies, it is clear that from the nature of the substance experimented upon, and the extreme difficulty of maintaining constant conditions, errors are apt to creep into the work. But the results given in Table III. as well as later determinations undoubtedly point to the existence of such a law as has been quoted.

The relation between diameter and life having been investigated, experiments were then made to determine the curve for current and mortality of the pencil, when the voltage is kept constant. For this purpose a number of moulded high-tension carbons of the brand E were used. To secure uniformity in the + and − pencils, a 12-inch stick was broken in half, one portion being used as the upper, the other as the lower carbon. The length of each run was an hour. Current and potential were read every two minutes and the mean taken. Table IV. gives the data from which the curve for current and mortality (Fig. 1) was plotted.

Table IV.—*Life with Different Currents and Constant Potential.*

Carbon.	Diam. mean inches.	Resis. ohms.	Initial wt. + grms.	Initial wt. − grms.	C. amperes.	P. D. volts.	Loss wt. + grms.	Loss wt. − grms.	Life per inch. Carbon burned hours.	Life − / Life +
E. Moulded high ten.	·518	·199	30·20	21·15	6·02	49·3	4·48	2·76	·6723	1·62
,, ,,	,,	,,	25·72	18·38	7·04	49·7	4·87	3·19	·6047	1·54
,, ,,	,,	,,	20·85	15·19	8·01	49·9	5·42	3 25	·5622	1·66

A series of tests was now made with constant-current and varying voltage. The current in this case was maintained at 10 amperes, and the range in tension was from 40 to 60 volts. Carbons of the same type as in the last instance were used. In Table V. are given the figures for these runs, and Fig. 2 shows the curve for voltage and mortality.

In the curves (Figs. 1 and 2) the ordinates represent the life of an inch of carbon in minutes. Reference is made not to the mortality of the + pencil, but to the total amount of carbon burned in the lamp. The last two columns in Table V. have been corrected for diameter and resistance of the pencil, the diameter and resistance respectively of the carbon that was burned at 10 amperes and 45 volts having been taken as a standard, and the life of the other pencils reduced to a common basis from this, according to the law previously stated.

Very little has been published regarding the relative life of the + and − carbons. Those books in which the subject is alluded to, state as a rule that with direct currents the life of the upper carbon is about half that of the lower, provided both have the same length originally. In a recent publication* the general statement is made that "with continuous currents the + wastes twice as fast as the − carbon. With alternating currents the upper wastes 8 per cent. faster than the lower if the carbons are vertical; but at the same rate if horizontal." No experiments were made upon arc-light carbons fed by alternating currents; but an investigation of the relative loss of the + and − pencils with direct currents gave quite interesting results. Table VI. shows that the plus carbon may burn away about as fast as the minus, or may waste more than three and a half times as quickly.

Three sets of experiments were undertaken to determine the elements that effect this ratio. 1st, Effect of changing the diameter and resistance of the pencils with constant current and potential. 2nd, Influence of change of current with constant potential. 3rd, Change of potential with constant current.

For determining the influence of diameter and resistance upon the relative life of the plus and minus carbons, a number of moulded high-tension pencils of the brand A were used. The carbons were supposed to have been taken from the same "batch," and were burned with a current of 10 amperes and a potential difference = 50 volts.

Examining Table VII., which gives the results of measurements we note that $\frac{\text{life}-}{\text{life}+}$ appears to become greater with increase of diameter of the carbon. It is probable that the inequality in the diameters of the plus and minus pencils respectively, as well as the difference in the resistances of the two carbons of a set explains, to a large extent the cause of this increase in the ratio. For, assuming that under the conditions maintained, the life of a carbon varies directly with its diameter and inversely with its resistance, the data (Table VII.) indicate that if the diameters and resistances respectively of the plus and minus carbons were the same in each run, the ratio would be practically the same for all sizes of carbons. This is brought out in the last column of the table, which gives the corrected values of $\frac{\text{life}-}{\text{life}+}$.

Reference to the last column of Table IV. will show that a change in the current, other conditions remaining the same, probably has no effect on the ratio $\frac{\text{life}-}{\text{life}+}$. For when a current of 6 amperes was used, the ratio was equal to 1·62; at 7 amperes the ratio dropped to 1·54; it then alternately increased and decreased to 13 amperes. Hence it may be said that if all errors of observation, as well as those due to irregularities in the carbons, could be eliminated, the $\frac{\text{life}-\text{carbon}}{\text{life}+\text{carbon}}$ would be found to be constant.

* Munro and Jamieson's Electrical Rules and Tables 1889.

Digitized by Google

The last column of Table V. contains the data for $\frac{\text{life}-}{\text{life}+}$, with different potential differences and constant current. From these calculations it appears that the ratio depends on the potential difference, and that the greater the potential difference the more nearly does the former approach unity. The curve plotted from the figures in Table V. is given in Fig. 3, the abscissæ being volts, and the ordinates representing the ratio of the life of the minus to the life of the plus carbon.

Thus the causes that influence the relative life of pencils of the same diameter lie chiefly in the difference in the resistance of the carbons and the variations of potential difference.

Judging from existing theories of the arc, it was thought that blowing the latter with a magnet during the runs would relatively increase the life of the plus carbon. The experiment was tried, and the reverse was found to take place, *i.e.*, the ratio $\frac{\text{life}-}{\text{life}+}$ increased while the life of the minus pencil was not much affected.

Efficiencies.

Two methods of determining the efficiency of each set of pencils were employed. The first was the method used by Mr. Merritt in obtaining the efficiency of the incandescent lamp,* and subsequently by Mr. Nakano in his work on the efficiency of the arc-lamp.† The second dealt with candle-powers, and will be referred to in the discussion of candle-power measurements.

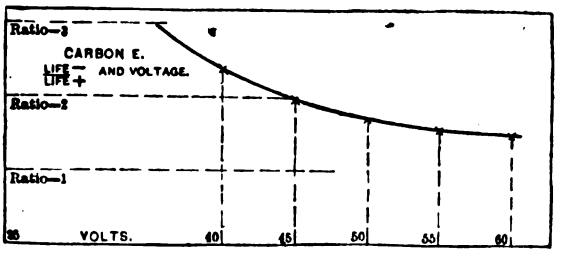

FIG. 3.

It may not be amiss to give here an outline of the first method employed. A Thomson lamp was mounted on a movable frame, and the rays from the burning carbons allowed to fall on the face of a thermo-pile, the latter being in circuit with a sensitive Thomson galvanometer. The deflection of the galvanometer was taken as a measure of the energy of the total radiation which fell upon the face of the pile. A cell containing a solution of alum was then interposed between the light and the pile, and the reduced deflection of the galvanometer noted. On the supposition that the alum cell cut off all the "dark heat," and allowed only the rays of the visible spectrum to reach the face of the thermo-pile, the last measurement would give the true value of the luminous energy emitted by the lamp. But a small percentage of the longer wave-lengths passes through the alum cell, and a large part of the luminous rays is cut off by its intervention. Correction having been made for these factors, the true values of luminous radiation resulted. A mechanism was provided by which measurements could be made at various angles below the horizontal plane without altering the distance between the centre of the arc and the thermo-pile. For the high-tension runs the lamp was fed by a current of 9 amperes, the potential difference between its terminals being kept at 45 volts. For low-tension tests, current = 21½ amperes, and potential difference = 30 volts. Note that the amount of energy expended in the low-tension lamp was $21\frac{1}{2} \times 30 = 645$ watts, while the high tension required but $9 \times 45 = 405$ watts. Although normally the former requires from 520 to 560 watts, unsteadiness of the light when the lamp was run below 21½ amperes made accurate measurements impossible.

Tables VIII. to XV. give the results of efficiency tests. In the column headed (L) are given the corrected values of deflections due to luminous radiation; the values of (T) refer to total radiation and the efficiency or luminous divided by total radiation = $\frac{L}{T}$. These tables furnish the data from which the curves (Figs. 4 to 11) were plotted. The radii show the positions for which measurements were taken, and distances measured along these lines from the origin to the *dotted* curves give the intensity of luminous and total radiation, respectively in each position. It will be seen that the distribution of total radiation differs considerably from that of luminous radiation; hence the efficiency, which is expressed by $\frac{\text{luminous radiation}}{\text{total radiation}}$ depends upon the angle of measurement. The full-line curves (Figs. 4 to 11) represent the efficiencies of the various carbons. In order to obtain the mean or hemispherical efficiency, the areas of the curves of luminous and of total radiation were found by means of the planimeter; now the ratio of the radii of two semi-circles whose areas are respectively equal to those of the curves of luminous and total radiation, is the value of the mean spherical efficiency. This value has been calculated for each set of pencils, and the results are given in Table XVI.; also in Figs. 4 to 11.

* Unplated. † Plated.

We notice that the horizontal efficiency is very small compared with the maximum; that relatively high efficiency in a *forced high-tension* carbon is obtained only at the expense of life; that a *moulded* carbon is, generally speaking, superior to a *forced* for high tension, and *vice versâ* for low tension.

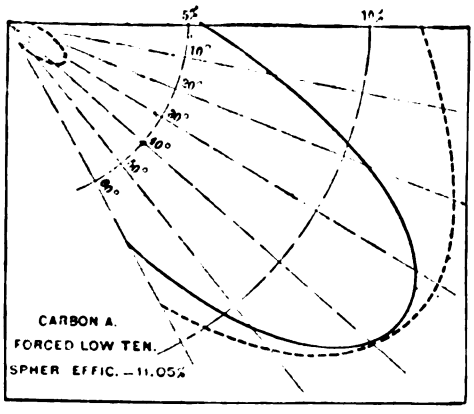

FIG. 10]

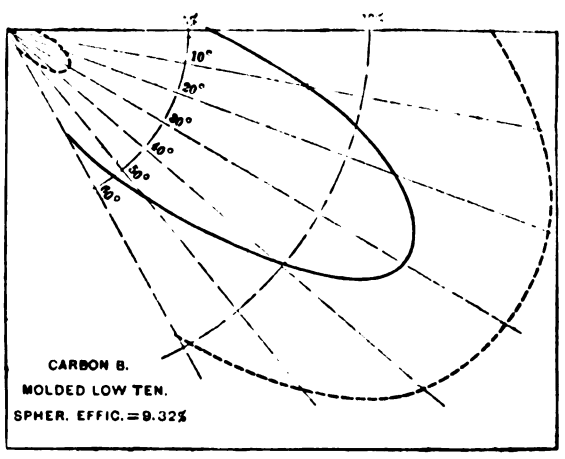

FIG. 11.

A point of interest brought out by these tests (Tables X. and XI. and Figs. 6 and 7) is the fact that while the life of a copper-plated carbon is greater than that of an unplated carbon of the same diameter and type, the mean spherical efficiency appears to be the same for both. Two sets of pencils of the brand B, the one unplated and the other plated, were burned to ascertain this relation. The results show that the horizontal and the maximum efficiency of the copper-plated carbons were a little greater than those of the uncoated pencils respectively, and the mean spherical efficiency in the latter case was very slightly less than in the former. As can be seen from Table XVI., the life of the "positive" plated pencil (12" long) was 10·64 hours, while that of the naked carbon was 9·16 hours, the current and potential difference having been the same for both cases. No positive explanation of this phenomenon has yet been given, but it appears that the actual amount

THE TREATMENT, REGULATION, AND CONTROL OF ELECTRIC SUPPLY BY THE LEGISLATURE AND THE BOARD OF TRADE.*

BY MAJOR P. CARDEW, R.E.

(Concluded from page 119.)

Safety Regulations.

These were embodied in the old Orders, and were in great detail, such points as the distance apart of terminals, and the maximum current to be taken from any pair of terminals, being specified. The pressure on distributing mains and service lines was not to exceed 200 volts continuous or 100 alternating; and no portion of an electric line placed above ground, and not enclosed, was to be at a pressure from earth exceeding 200 volts.

The St. Austell Licence of 1885 is, I think, the first licence or Order in which separate regulations have been issued; and the same form has been used in the Kensington and Knightsbridge Order of 1889 and the St. James's Licence of 1888, and nearly the same form in the Chelsea Order of 1886. These are more general in character. The limit of low pressure has been raised to 300 volts continuous, while alternating currents are not to be used except with the approval of the Board of Trade, and under such further regulations as may be considered necessary.

A very important innovation has also been introduced in these regulations, providing that the undertakers shall cut off any consumer upon whose premises they find that a leakage exists having resistance to earth of less than 5,000 ohms. This is to some extent a departure from the policy of the Board of Trade to leave the regulation of the circuits on private premises to the insurance companies; but, unfortunately, electricity does not conform to these arbitrary distinctions, and a bad leak on a consumer's premises is just as much a source of danger and difficulty as one on the main outside—in the case of direct supply systems, at any rate.

The general regulations for overhead wires, made under Section 4 of the Act of 1888, are pretty generally known at the present time, and I need not dwell upon them. As you are aware, they were thoroughly revised by your Council, who have also given their powerful assistance to the Board of Trade in the matter of some new proposed general regulations for undertakers of electrical supply, which, however, are still under discussion. The principal features of the new draft regulations are—(1). The division of the various systems of supply into three classes, viz., low pressure, high pressure, and extra high pressure; low pressure to extend to 300 volts continuous or 150 alternating; high pressure, from above this to 3,000 volts, either continuous or alternating—that is, to as high a pressure as we have had practical experience of in distribution systems; extra high pressure, above 3,000 volts. (2). A general provision that where high-pressure conductors or apparatus are exposed in such positions as to be possibly touched by persons, or brought into contact with low-pressure conductors, they shall be entirely enclosed in strong metal casing efficiently connected to earth.

Supply Regulations.

These have been subjected to less alteration than the Safety Regulations. The variation of standard pressure permitted has been reduced, and in the new draft it is proposed, as already stated, to introduce the idea of a pressure to be declared at the consumer's terminals, which is not to vary more than 4 per cent., and the variation of which may be tested for the consumer on his application by the electric inspector. It is also proposed to take advantage of the powers of the transformer system, and provide that the consumer supplied from a transformer on his premises shall have the choice of two pressures given him, one about half the other.

No doubt many of the regulations that have been made are open to criticism: but I would point out that they are in every case the result of very careful consideration, and that observations on them from many different points of view have been submitted, and given, as far as possible, their due weight. It is not unlikely, therefore, that a criticism, even from a high electrical authority, may be unjust and erroneous, from the critic not being acquainted with all the circumstances and conditions which have guided the Board of Trade; and it should also be borne in mind that the Board are empowered to alter any regulations issued by them, or to repeal them and issue fresh ones, should the progress of electrical discovery and further experience make such a course desirable. And whatever imperfection may become apparent in these regulations, I can confidently affirm—and I feel sure that this proposition will receive the support of those among you who have experience of its methods of procedure—that the Board of Trade has been guided solely by the desire to do the duty imposed upon it by Parliament, and to serve the best interests of producers and consumers alike.

The Standardising Laboratory.

And now, I should like to say a few words about the standardising laboratory. You are probably aware that the Board of Trade have, in deference to the wishes of the large body now interested in practical applications of electricity, as expressed by a powerful deputation to the President last year, undertaken to provide something in the nature of a testing establishment for instruments intended for the measurement of electrical quantities, analogous to the Standards Department of the Board of Trade for weights and measures of the more gross and material quantities. They have also taken powers under the Weights and Measures Act of last Session to undertake such testing and verification, and to charge fees for it; so that these verifications, whatever their scientific value, will possess a legal value. A general scheme for the scope and working of this laboratory was drawn up very carefully last year by a committee of your Institution, in connection with which I should like to mention especially the hard work done by Dr. Fleming, in a cause which he has given abundant proof that he has at heart. The general idea embodied in this, in which I personally entirely concurred, is that the thing should grow from small beginnings. This, I think, is the English way, and I need only point to the present position of our own Institution as an example of its success. Our more impressionable neighbours on the other side of the Channel like to start these things in a different way. They must have something grand and striking, and of course there is much to be said for this view, if you have the means to carry it out; but it sometimes leads to, as it were, setting up a steam hammer to crack nuts. No doubt the steam hammer can do it very well, but a pair of nut-crackers is cheaper. Now I can promise that there will be nothing grandiose about our laboratory—we are starting with a very ordinary pair of nut-crackers. It is hardly necessary to observe that the small beginnings idea was the part of the scheme most to the taste of the Treasury; in fact, to use an electrical metaphor, my Lords would have liked our electrical particle to have acquired its potential of doing work by starting in the legitimate way at an infinite distance from the charged body (the national purse), and to have been a long time on the road too. However, let us not forget that if we are electricians we are also taxpayers!

Now, what we hope to do in this laboratory is, first of all, to get the true values of the electrical units, within a very small possible percentage of error. We are not tied to the so-called legal units, which I may remark have no legal value in England; but, with the assistance of Lord Rayleigh and the Standardising Committee of the British Association, we hope to get even nearer the truth than was arrived at with this set of units. Secondly, having got there, we hope to keep there by well-devised checks and frequent reference to the fundamental measurement. This, as we are at present advised, will be the measurement of current by the quantity of silver deposited from solution in a determined time. Thirdly, as soon as we are satisfied that sufficient accuracy and permanence has been arrived at with our instruments and methods, we shall be ready to receive instruments, either for simple verification in the case of ordinary commercial instruments, at a small charge for each reading, or for thorough testing and certification in the case of instruments submitted as sub-standards. The rules and charges have not yet been drawn up, but it is probable that instruments will be required to be marked with a clear and intelligible scale—whether of degrees or volts or amperes, &c., is quite immaterial; the extreme range of the instrument must be given approximately, and whether it is intended for alternating or continuous currents or pressure, or for both. The reading given by the instrument on its own scale for each current or pressure asked for will be taken, probably, in all cases both with increasing and with decreasing readings. No extreme accuracy will be guaranteed for these readings, but it is hoped not to exceed an error of $\frac{1}{4}$ per cent. from the true value. Of course, in the case of ordinary commercial instruments, we should give no sort of guarantee that the instrument will remain constant for any time, or under different conditions. Sub-standards will be subjected to long and rigorous testing, including the determination of their variation under different temperature and the permanence of their constants. I am afraid, however, that in most cases there will be some difficulty in giving any guarantee of the constancy of an instrument after it has passed out of our hands.

The power for laboratory purposes will be supplied from two batteries of accumulators—one of four very large cells simply to give steady continuous currents up to 2,000 amperes; the other, consisting at first of 100 smaller cells, will be used directly for continuous pressures up to 200 volts, and also to run the machinery. The machinery referred to is two pairs of dynamos, one of each pair being energised by the cells as a motor and driving the one connected to it as a generator. One of these

* Paper read at the Institution of Electrical Engineers, on May 15, 1890.

Digitized by Google

generators will be an alternate-current machine, and the other a high-pressure continuous-current machine. In connection with the alternate-current machine we shall have a set of transformers. In this way we hope to get currents practically as steady as if taken direct from the accumulators, and in the case of alternating currents and pressures any frequency within the limits of practice. The limits we propose to work up to at first are—

Continuous current ...	...	...	2,000 amperes ;
,, pressure ...	...	...	2,000 volts ;
Alternating current ...	...	...	500 amperes ;
,, pressure ...	...	...	2,000 volts.

The building and alterations necessitated are now nearing completion, and we hope to have the laboratory in working order in about two months' time.

LEGAL INTELLIGENCE.

Crompton and Co. (Limited) v. the Elieson Electric Company (Limited).

In the Queen's Bench Division, on Friday, Mr. Baron Huddleston and a special jury resumed the hearing of this case.

Mr. THOMAS BRICE GOWER, secretary of the Elieson Electric Company, stated that the works at Romford-road, Ilford, were erected expressly for the supply of electric engines to the North Metropolitan Tramway Company, and that in consequence of the arrangement between the defendants and the tramway company falling through, the works had been rendered useless, and the defendants had sustained a heavy loss.

Cross-examined by Mr. MOULTON: In the agreement between the defendants and the tramway company the latter had to keep the whole of the tram lines in proper repair. The siding where the wheels of the engines were broken through the defective connection was laid down by the permission of the tramway company by one of that company's usual contractors. The contractors who laid down the siding were competent persons for laying lines for horse traction, but he did not know that they had ever had any experience with regard to mechanical traction. He denied that the defendants had a breakdown with their armatures. The breakdown in 1887 was under the old company, and not the present one. One of the acts of negligence he alleged against plaintiffs was that they sent out an engine with a washer so deep that the teeth of the rack of the engine did not bottom properly, and consequently they got broken. He did not admit that this washer was the same as had been used by the defendants for months, but he would not swear that it was not. He also alleged that it was an act of negligence on the part of the plaintiffs to use the starting switch for reversing the engine. He denied that in the defendants' line a large driving switch was in common use for reversing.

Mr. LESTER, a member of the defendant company, gave evidence with reference to the agreements made by the defendants with the North Metropolitan Tramway Company and the plaintiffs respectively.

Mr. BOUSFIELD, mechanical engineer, said he had had a large experience in the business, and had examined the machinery of the defendants' engines. He considered the defendants' system a good one. The breaking of the engine wheels was due to the points being wrongly constructed. With regard to the breaking of the teeth of the rack, the teeth, instead of going home, only touched on the tips, and this was due to the motor being raised too high by the washer.

Prof. SILVANUS THOMPSON gave evidence to the effect that he had examined the defendants' system, and that in his judgment it ought to work well for the running of electric engines. With regard to the breaking of the teeth of the engine rack, he attributed that to two causes—the insufficient setting of the guard, and the motor being improperly started with too strong a current.

Mr. ASHER said the engines in question were constructed for the defendants under his superintendence, and he firmly believed the system was a good one in all its details. He agreed in substance with what the two previous witnesses had stated.

This concluded the defendants' case.

Mr. MOULTON, in opening the case for the plaintiffs, said the little mishaps and accidents that had occurred to the defendants' engines were such as generally overtook the pioneers of any new form of locomotion. The plaintiffs merely acted as managers of the Plashet works for the defendants, and none of the defendants' contracted arrangements were communicated to the plaintiffs. Messrs. Crompton and Co. were electrical engineers of very wide experience and very high standing in their profession, and they occupied towards the defendants the position of managers, and if they were going to say that managers were responsible for all carelessness and negligence on the part of workmen under them, then the position of managers would become intolerable. Everyone of the men who worked for the plaintiffs had previously been in the employ of the defendants, and had been in the habit of performing the work of charging the accumulators with electricity to the extent of twenty times a day. Therefore they must be considered to be experienced and reliable workmen, and the plaintiffs, as managers, were entitled to rely upon them doing their work in a competent manner. They might just as well say that the manager of a large tramway company was responsible if one of the horses of the company did not get its feed, as to say that the plaintiffs were responsible for every act of the workmen under them. The accidents which had occurred were such as were inevitable in starting an invention of this kind. With regard to the siding, the usual course in laying down points was to run an engine up and down the line to see whether it cleared the points properly, and when the contractors were fixing the points at the works by the order of the defendants the plaintiffs placed at their disposal an engine for that purpose. Therefore, it could not be said that the plaintiffs would be guilty of any negligence. As to the alleged insufficient storage of electricity, the learned counsel said the plaintiffs took over the defendants' men, who had had experience in this kind of work, and that therefore the plaintiffs were justified in relying upon those men doing the work properly.

The case was then adjourned till Saturday.

SATURDAY, June 7th.

On the case being resumed on Saturday,

Mr. R. E. B. CROMPTON, of the plaintiff company, was called, and stated that during the negotiations with the defendants there was no question whatever with regard to his firm taking over the risk of the defendants' business. The written agreement which had been put in fairly represented the conversation which passed at the time when he attended the defendant company's Board meeting. It was the custom of the plaintiffs to send the defendants weekly accounts and the wages sheets, and the defendants sent back cheques for the amounts. The plaintiffs engaged some men beyond those already in the employment of the defendants. The stopping of one of the engines did not occur in consequence of the accumulator being insufficiently charged. He believed the accident occurred through the breaking of a connection. The small-power switch was a dangerous addition to an engine, and was unnecessary. He would work by switching on and off with the main starting switch. The contract between the defendants and the North Metropolitan Tramway Company was not made known to plaintiffs. It would cost about 30s. to repair the teeth of the rack.

Cross-examined by Mr. FINLAY: Personally he gave very little attention to the Plashet Hall works. The actual superintendence was left to Mr. Chamen. He held that the breakdown took place in consequence of the breakage of a connection. The plaintiffs had evidence of that, and also that the accumulator was properly charged.

Mr. WILLIAM CHAMEN stated that he had been with the plaintiffs for nine years, and that for four or five years he had acted as manager of the installation department. He had had great experience in electrical matters. Seventeen men at the works were employed by him; but the majority of them had previously been employed by the defendants. So far as he knew, they were competent to perform the work he allotted to them. On Saturday, September 8th, running was recommenced, and the accumulators were charged by his directions. Mr. Howes, the foreman, had the superintendence of the operation, and proper appliances were provided and used. The mishap to one of the engines did not arise from the accumulator being insufficiently charged, but from the breakage of a connection. When the siding at the works was being laid he placed an engine at the disposal of the contractors on more than one occasion, in order that the points might be tested. The engine was run forwards and backwards over the points. He remembered the breaking of the wheels of one of the engines. He was close by when the accident occurred, and a broken piece of the wheel was found on the road. The washer was never touched. When the engines came under the supervision of the plaintiffs the small-power switch was attached to all of them. He made inquiries of Mr. Howes, the foreman, and of the drivers, respecting them, and they all complained that those switches were continually getting out of order. He satisfied himself that it was easy to reverse with the main switch, and that the small-power switch was unnecessary.

Cross-examined by Mr. FINLAY: With regard to the breakage of the teeth of the rack he thought that the first breakage was probably due to slipping. If when the first tooth had broken he had removed the whole of the remaining teeth the accident would have been prevented. He knew of the existence of the washer, but he was at the works to see that the engines were in a proper state to work and not to alter the gear. He heard that the washer was reduced after the accident, but he had no personal knowledge of it. The motion was gentler with the large-power switch. He took charge of the engines at Stratford before they were moved to Plashet Hall.

Prof. ALEXANDER KENNEDY, F.R.S., had been down to Plashet Hall works twice and seen the defendants' engines. He made such experiments as he could, and was satisfied that there was sufficient spring in the upper part of the engine frame to allow the pinion teeth to move in the rack up or down a little less than a quarter of an inch. He believed that the motion could take place through the jolting on the road. It would be prudent to leave a space between the end of the teeth and the bottom of the space on the rack; that would be a matter determined by experience in working. If an engine had been working well for six months he would certainly not take the responsibility of altering it. With regard to the relative advantages and disadvantages of starting an engine with the ordinary driving switch, or having a small-power switch, he thought on theoretical grounds there was no doubt that the small-power switch would not be as good as the main switch used in the manner in which he saw it used at the works. There was no difficulty in using it in that way. If he had the management of such engine he had no doubt whatever that he should start with the main switch.

Cross-examined by Mr. FINLAY: In order to ascertain that the upper part of the engine would dip to the extent he had mentioned, he lifted up the upper end by means of a bar. He did not ascertain by actual experiment that any jolting on the road would cause a dip to such an extent; in fact, he had not seen one of the engines running on the road.

The further hearing was adjourned till Monday.

Digitized by Google

MONDAY, June 9th.

On the resumption of this case, Mr. A. J. HOWES said that in the early part of 1888 he was in the employ of the defendants, being foreman under Mr. Gower. When the Plashet Hall works were started under the management of the plaintiffs he was transferred to those works, and he continued to work under the plaintiffs until September, 1888. At the Plashet Hall works he took his directions from the plaintiffs and sometimes from Mr. Gower. Witness looked after the charging of the accumulators. He was accustomed to do that kind of work when he was working under the defendants earlier in the year.

His LORDSHIP: What do you suppose was the cause of the failure of the accumulators?

WITNESS: The accumulators were properly charged. I was at Stratford when the engine arrived, and I attribute the accident to the breaking of a connection through the vibration of the engine while going along the road. Witness said he was present when one pair of wheels broke at the points. From what he saw he concluded that the points had broken the wheels. He remembered a new set of teeth being placed on the rack of one of the engines by Mr. Chamen's direction.

Cross-examined by Mr. FINLAY: Prior to the engines stopping running in March, 1888, he had been in the employ of the defendants a fortnight or longer. That was the extent of his knowledge of the defendants' system.

Two drivers were then called, and gave evidence that the main switch was commonly used because the small-power switch was continually getting out of order.

This concluded the evidence for the plaintiffs.

Mr. FINLAY said he should contend on behalf of the defendants that if an expert was employed for the purpose of putting certain machinery in order, or to conduct a particular experiment, and it was well known to him that a failure of the work or experiment would result in loss to his employer, the employer was entitled to recover damages.

His LORDSHIP said he should hold that that was not so.

Mr. GRAHAM, in addressing the jury on behalf of the plaintiffs, contended that his clients had been guilty of no negligence, and that even if they had, the defendants were only entitled to recover the trumpery sum of £9. 1⁰s. He also denied that at the time of the arrangement between the plaintiffs and the defendants the defendants had any contract with the Metropolitan Tramway Company.

Mr. FINLAY, on behalf of the defendants, said the plaintiffs had clearly been guilty of negligence in the supervision and management of the defendants' works, that the mishaps were the direct result of that negligence, and that consequently they (the plaintiffs) were liable to pay damages.

His LORDSHIP, in summing up the whole case, said the defendants had admitted the plaintiffs' claim to the extent of £384, and therefore the plaintiffs were entitled to a verdict for that amount. The next question was whether the defendants were entitled to recover anything from the plaintiffs; and to decide that question they must first ascertain what was the exact position in which the plaintiffs stood to the defendants—whether they were merely managers, or whether they were contractors. The learned Judge then proceeded to deal with the agreements between the plaintiffs and the defendants, and the evidence which had been given both in support and against the alleged acts of negligence.

The Jury retired, and after a short consultation they returned into Court with a verdict for the plaintiffs in the claim for £384, and for the defendants on the counterclaim for £184. They found that the plaintiffs were contracting parties, that they were guilty of negligence as regarded the accumulators and rack teeth, but not as regarded the wheels and the points of the siding.

His LORDSHIP gave judgment accordingly, and certified for the special jury.

Mr. MOULTON asked that the defendants might be deprived of their costs. While they claimed £10,000, they had recovered only £184.

His LORDSHIP said it was a sound rule that costs should follow the event, and therefore he declined to deprive the defendants of their costs.

TELEGRAPHIC RATES TO AUSTRALIA.

The following letters, relating to the subject of the reduction of the Australian Cable rates, may prove of interest. The first of these letters, which has not before been published, was addressed to the Agents-General of the Australian Colonies by Sir John Pender on the 25th ult.; and the remainder have appeared in *The Times*; the second and third on the 7th inst., the fourth on the 9th inst., and the last in yesterday's issue.

GENTLEMEN: Since our conference yesterday, I have had a meeting with our allied companies, which leads me to believe that we shall be able to eventually come to an understanding with them, more particularly the Eastern and Indo-European Telegraph Companies. The Persian Gulf department may be more difficult to deal with; but as that administration is practically the Indian Government, probably the influence of the Colonies upon India may be effectual in bringing them also into the proposed arrangement. However, there is no time to be lost; and it is very important, while the Conferences are sitting in Adelaide and Paris, that the principle should be definitely settled.

Therefore, believing that the present difficulties will be overcome, I am prepared to accept the 4s. tariff, although it involves a very large additional loss in the first instance. Still, I believe that the lower rate will probably more quickly recoup the loss than the higher tariff; and as the 4s. rate was embodied in our first proposition to the Colonial Governments, and has evidently made an impression on the minds of the Colonists, we are the more anxious that whatever arrangement is made should command the approval and support of all parties concerned.

The term for testing the effect of a cheap tariff will be for one year certain; but if at the end of that period, as I have stated in my telegram to Adelaide, our loss is not a serious one, we shall have no objection to extend the term to three years; at the end of which time, if it is found that the loss is likely to be recouped within a reasonable period, the arrangement shall be continued for the remainder of the term of our subsidy agreement with the Colonies.

It is understood that the reduced tariffs come into force on and from the 1st of January next. This will give ample time for the financial arrangements with the different Colonial Governments and Her Majesty's Government to be made; but these, of course, rest entirely with the Governments themselves.

I am, Gentlemen, your obedient servant,
JOHN PENDER, Chairman
The Eastern Extension, Australasia, and China Telegraph Company, London, E.C., May 25.

P.S. I enclose a copy of the telegram I am to-day forwarding to our agent at Adelaide, giving the Company's decision in regard to Mr. Derham's resolution.

The Agents-General of the Australasian Colonies.

[Copy of Telegram.]

25th May, 1890.

Director-General Extension Company, to Director, Adelaide.

After further conferences with Agents General, and rather than lose present favourable opportunity of settling matters, Chairman willing to waive conditions specified in telegram to Todd, 23rd, and will agree to a

4s. 0d. tariff for ordinary,
3s. 6d. „ Government, and
1s. 10d. „ Press messages.

Governments should remember that the half rate is only given over the extension lines in consideration of the subsidy which the Extension Company receives from the Colonies, and therefore impossible to reduce Government messages below 3s. 6d. With regard to duration of experiment, Chairman must adhere to previous proposal—namely, if at end of first year no serious loss involved, Company will continue experiment for another two years; but this must remain at Company's option. Should loss be nearly recouped at end of three years, Company will extend arrangement for remainder of subsidy term. Above figures are based on South Australia accepting transit rate of fivepence.

SIR: My attention having been drawn to the foot-note to an article appearing in the current number of the *Nineteenth Century*, purporting to have been written by Mr. Henniker Heaton, M.P., and in which the writer says that, "Nevertheless, I have been able to take effective outside action, which has resulted in wringing from these hard-fisted associations a reduction of the rate to Australia to 5s. per word," I have no hesitation in saying that the statement is absolutely without foundation, as all the other parties to the arrangement can readily testify.

The 4s. rate now provisionally arranged between the companies and the Adelaide Postal and Telegraph Conference is the outcome of negotiations conducted between myself and the several Agents-General of the Australasian Colonies prior to, and entirely independent of, the Paris Telegraph Conference, to which it has not so far been submitted, it being quite beyond the control of that body.

I am, Sir, your obedient servant,
JOHN PENDER, Chairman
The Eastern Extension, Australasia, and China Telegraph Company, London, E.C., June 5.

SIR: During the past five years I have in Parliament, in the Press, and on public platforms, and as delegate of an Australian Government at the Berlin Conference, denounced the monopoly enjoyed by Sir John Pender, and the monstrous charges made by him for cable messages to Australia and India. In a letter to *The Times* on May 3rd I pointed out the enormous profits realised, and urged a reduction. On Saturday, May 10th, I telegraphed to Australia that a reduction of telegraph rates from 9s. 4d. to 5s. per word would take place, and a telegram appeared in the Australian newspapers to the same effect on Monday morning (if not delayed in transit), in which telegram my name appears. On Monday afternoon, May 12, Sir John Pender met the Agents-General, and on Tuesday, May 13th, Sir John Pender wrote agreeing to reduce his own charges to Australia from 9s. 4d. to 5s. per word, under certain conditions. Sir John will have no difficulty in understanding how I managed to force him to reduce the rates, if he will make inquiry; but I think I have proved that before his meeting the Agents-General in conference I had made up my mind to force him to reduce the rates, and that I knew I should succeed. After the final settlement I pledge myself to produce conclusive evidence from independent witnesses of the truth of these statements. But I do not wish a personal dispute between Sir John Pender and myself to cause a rupture in the arrangements, particularly as the question is now under review at the Colonial Office.—Your obedient servant, J. HENNIKER HEATON.

SIR: When Mr. Henniker Heaton attempts to appropriate the credit of having broken down the monopoly of telegraphic communication to Australasia, and to have effected by his own unassisted efforts a widespread reform in one of the most important departments of modern civilisation, it is time that the absurdity of any such pretensions on his part should be

Digitized by Google

exposed. Sir John Pender's letter, which you publish this morning, shows conclusively that Mr. Henniker Heaton has not been in the remotest degree instrumental in bringing about a reduction in the cable rates to Australasia. If any further evidence be required, it will be found in Mr. Henniker Heaton's own letter on the subject, which also appears in your issue of to-day, in which he alludes to the proposed rate as being 5s. per word, instead of 4s., as stated by Sir John Pender, thereby exposing his ignorance of the subject upon which he is writing.

It may be of interest to your readers, now that Mr. Henniker Heaton's claims have been disposed of, to know the means by which the reduction from about 9s. 4d. per word to 4s. in the cable rates to Australasia has been effected.

In 1886 the Pacific Telegraph Company was formed by Mr. Randolph Want, of Sydney, and myself, having for its object the laying of a cable from Vancouver Island to Australia. Among the signatories to the articles are Sir Donald Smith, Mr. Sandford Fleming, Sir Samuel Wilson, Sir James Corry, Sir William Clarke, Sir Daniel Cooper, and the late Lord Milltown. When the Colonial Conference assembled in London in 1887 a formal proposal was put forward by this Company to the several Colonial Governments, offering to lay a cable from Canada to Australia, and to reduce the tariff to a maximum of 4s. per word from this country to Australasia, in consideration of a certain subsidy for 25 years.

It was, of course, necessary that such a proposal should be met by the Eastern Extension Company, who accordingly followed suit by offering to reduce their rates, under certain conditions, to 4s. per word.

The proposal of the Pacific Telegraph Company is still under the consideration of the Canadian and Australasian Governments. Last year the Canadian Government invited the Governments of the Australian Colonies to meet in a Conference at Sydney to discuss, among other matters, the question of the Pacific Telegraph Company's proposal. The Conference has been postponed, owing to the question of the inter-colonial federation of the Australasian Colonies having for the time being superseded all other considerations. In the meantime the survey of the proposed cable route has been practically completed. Every day that passes exposes more clearly the ineradicable defects in the existing system of cable communication to the East, and everything points to the certainty that such a hiatus in the world's telegraphic system as is now represented by the Pacific Ocean is quite incompatible with the requirements of modern civilisation, and especially with the rapid expansion of Canada and Australasia. That the Pacific cable will before long be laid is a certainty to which no one is more alive than Sir John Pender, and it is to the considerations set forth above, and to no other, that his being forced to agree to a reduction of over 50 per cent. in his Australian rates may safely be ascribed.—Yours, &c.,

34, Clement's-lane, June 7th. HAROLD FINCH-HATTON.

SIR: I can picture the amazement which those aquainted with the genesis of the Pacific Telegraph Company must have experienced on reading the statements of our secretary in that association, Mr. Finch-Hatton, in his letter to *The Times* this morning.

He says that to the formation of the Pacific Cable Company, and not to me, the credit is due for forcing Sir John Pender to agree to the reduction in Australian cable rates. The letter also contains the following remarkable paragraph:—

"In 1886 the Pacific Telegraph Company was formed by Mr. Randolph Want, of Sydney, and myself (Mr. Harold Finch-Hatton), having for its object the laying of a cable from Vancouver Island to Australia. Among the signatories to the articles are Sir Donald Smith, Mr. Sandford Fleming, Sir Samuel Wilson, Sir James Corry, Sir William Clarke, Sir Daniel Cooper, and the late Lord Milltown."

Incredible as it may appear, the articles of association contain my name as one of the original founders, and it was wilfully suppressed by Mr. Finch-Hatton in his letter to you. My solicitors even drew up the articles. I send you the document for inspection. As secretary to the Company, Mr. Finch-Hatton sends me periodically a summons to attend the general meetings.

In 1882 I was looking about to find a means of breaking up the monopoly enjoyed by Sir John Pender. Captain Audley Coote, M.L.C., of Tasmania, suggested the Pacific cable, and at his instance I formed in 1884-5 a Company in London, consisting of Lord Milltown, Sir James Corry, M.P., the Right Hon. H. Cecil Raikes, M.P., Mr. H. G. Reid, M.P., Lord Radnor, and myself. These names, with that of Mr. George Coote, as representing Captain Audley Coote, were placed before Messrs. Wilson, Bristowe, and Carpmael, the eminent solicitors, who drew up the Articles of Association. Mr. Raikes was appointed Postmaster-General, and retired before a meeting was held. We then found that another company had started with a similar object. We amalgamated our forces. If the reduction of rates is due to the existence of the Pacific Telegraph Company, I am still, on Mr. Finch-Hatton's own showing, more responsible than anybody for "the credit of having broken down the monopoly" in question.

Just one more exposure of Mr. Finch-Hatton's want of candour, and I have done. He writes:—

"If any further evidence be required it will be found in Mr. Henniker Heaton's own letter on the subject, which also appears in your issue of to-day, in which he alludes to the proposed rate as being 5s. per word, instead of 4s., as stated by Sir John Pender, thereby exposing his ignorance of the subject upon which he is writing."

Well, in the *Times* of May 16th, Sir John Pender's letter to the Agents-General contains these words:—"The Eastern Extension Company is prepared to reduce the tariff between Europe and Adelaide, from January 1st next, from 9s. 4d. to 5s. per word."

What, then, becomes of the accusation of ignorance made by Mr. Finch-Hatton? Let me recommend him in return to cultivate modesty and accuracy.—Yours, &c., J. HENNIKER HEATON.

June 9th.

PARLIAMENTARY INTELLIGENCE.

Central London Railway Bill.

On the order for the consideration of this Bill in the House of Commons on Friday evening last,

Mr. BOULNOIS moved that the Bill be considered this day three months. There was the strongest possible objection to the proposed railway on the part of the shopkeepers of Oxford-street. They objected that an experiment such as this involved should be made in such an important thoroughfare as Oxford-street, Holborn, Newgate-street, and King William-street. They objected to such a line of route being handed over to a body of speculators, who had not the slightest knowledge of the scheme they proposed to introduce. He said that advisedly, because this was an electric railway, and there was no experience in this country of the success of such a railway. There seemed to be no necessity for it at all, because it would not relieve the vehicular traffic, nor would it do anything for the cross traffic from north to south, which was the source of so much danger and delay, and it was, moreover, not a railway which would facilitate intercommunication of passengers by different railways, such as the Metropolitan and District Railways afforded.

Mr. G. BRUCE, in seconding the motion, urged that Holborn was not a district where an experiment of this kind should be tried. The Select Committee which had considered this Bill had not been able to make up their minds about it, because they had inserted a clause preventing the promoters issuing their prospectus or raising their capital till after three months' experience of the working of the City and Southwark Subway. That showed that the Committee itself had not been satisfied this was a practicable scheme.

Mr. T. H. BOLTON suggested the adjournment of the debate in order to give the local authorities or freeholders interested an opportunity of considering the question of obtaining compensation from the promoters for the use of the ground underneath the roadway.

Sir C. LEWIS submitted that no public ground had been suggested why the ordinary course should not be taken in connection with the present Bill, since it had been duly considered by a Committee of the House. The great problem to be solved was how to manage the ever-increasing traffic of the metropolis.

Mr. P. STANHOPE said they had heard nothing from the opponents of the Bill which would justify its rejection, and he hoped no more time would be wasted in the discussion.

Sir H. SELWIN-IBBETSON must point out with regard to the proposal to shelve this Bill for six months that the Holborn Division supported this Bill, while the St. Giles Division, which opposed the Bill on clauses, had withdrawn their opposition when the clauses were agreed upon. The proposal, therefore, to reject the Bill was made on insufficient evidence. His advocacy of the Bill was based on the inadequacy of the accommodation of the traffic. He believed that the scheme under the Bill would relieve the congested traffic, and he hoped the House would support the decision of the Committee.

Mr. W. JAMES also supported the Bill, and said that it must be apparent to everyone that it was necessary to do something to relieve the traffic. He regarded the opposition as rather of a selfish kind.

Sir J. PULESTON pointed out that three of the most eminent architects and engineers had given their opinion that the line, if constructed, would involve no risk to St. Paul's, the character of the subsoil being favourable for the construction of a tunnel, and the distance it would be from the foundations of the building being sufficiently great. All the public bodies of the district were in favour of the formation of the line, which would be a great convenience.

Sir E. GREY, as one of the members of the Committee before whom the Bill came, said that the measure had been under their consideration for 13 days, and the decision which had been come to had been arrived at after a careful review of the whole of the evidence that had been laid before them. The opposition to the measure arose out of local and not wholly disinterested prejudice.

Mr. BRUNNER pointed out the danger of the House setting a precedent of handing over to private companies the land under the streets of the metropolis, which was of enormous value. In New York such land was disposed of for the benefit of the city.

Mr. CREMER, while in favour of the nationalisation of all our highways, hoped that the House would mark its opinion of the character of the opposition to the measure, which came from a handful of wealthy tradesmen, who allowed their selfish interests to outweigh the public convenience.

Mr. J. ROWLANDS said the House ought to express an opinion that in future when a Committee had to consider a Bill of this description it would be expected to make some terms for the community. In this case the Company proposed to go to so great a depth that they did not require to take any premises on the surface, and thus they avoided the ordinary difficulties of compulsory acquisition. But the community had some interests in these railways, which were the railways of the future, and it ought to be understood that in the form of a royalty or in some other way the rights of the community should be preserved, and should not be altogether parted with to private companies.

The motion was then agreed to, and the Bill was put down for the third reading.

Electric Lighting Acts Amendment (Scotland) Bill.—This Bill was read a second time in the House of Commons on Thursday last week.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 30, 1890.

Electrical Execution.—The Supreme Court of the United States has refused to grant the writ of error which was applied for in the Kemmler case. As might have been expected, the Court held that electrical execution was not such a cruel and unusual form of punishment as was intended in the prohibitory clause embodied in the constitution of the United States. Legal resources have now been exhausted, and it seems quite certain that Kemmler will meet his well-deserved fate by the means prescribed in the statutes, unless he should be pardoned—which is decidedly improbable.

Consolidation of Electrical Interests.—Rumours of consolidation between the Thomson-Houston Electric Company and the Edison Company have been revived, this time in more definite form and with some appearance of probability. If such a combination should be formed, it would leave the control of the electric lighting and power industries practically in the hands of two companies—the Westinghouse Company and the new combination. Whether the Westinghouse Company under those circumstances would fight or become a party to a great electrical trust remains to be seen. The Westinghouse Electric Railway Company is working actively to secure contracts; and although it is not yet ready to deliver the requisite machinery, it is likely that the early summer will see several Westinghouse electric roads.

The Rapid Transit Problem in New York.—There is great interest in New York just at present on the rapid transit problem. Suggestions are being continually made that the only solution of the above lies in a four-track underground railway, reaching practically the entire length of Manhattan Island. This view of the case is probably correct, for the elevated roads are totally unable to handle the enormous population that daily migrates back and forth in the business portion of the city. The surface roads are of little assistance, and unless the cable railway scheme at present before the public should succeed, and thereby delay the coming of genuine rapid transit, it is quite probable that steps toward an underground system will be taken in the near future. If anything of the kind should be attempted, it may be regarded as almost certain that electricity will be the motive power.

The Underground Mains Question in New York.—There seems to be great difficulty in securing underground conduits for the electric wires in this city, the subway companies being quite unable to furnish material fast enough to suit the Board of Electrical Control. Mayor Grant seems disposed to throw every possible obstacle in the way of the electric light companies. His latest move is an attempt to close the streets by forbidding the taking up of pavement for the purpose of making connections with subways. At the last meeting of the Board of Electrical Control he went so far as to demand from the Board and its experts some method for making connection for house service without moving the pavement at all. What might have seemed a righteous indignation in the early days of his proceedings against electric lighting, was, it is now evident, bitter personal opposition towards any propositions that come from the electric light companies. If the electric light companies were less scrupulous, perhaps work might proceed more rapidly.

CORRESPONDENCE.

THE PERMEABILITY OF IRON AT RIGHT ANGLES TO THE DIRECTION OF MAGNETISATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—Seeing the commencement of Mr. Kennelly's articles in last week's *Electrician*, and noting your editorial remarks on them, we think it might in some measure contribute to the elucidation of this matter if we detail to you some experiments made by us in March last.

Starting from the idea suggested by Mr. Swinburne during the discussion on Dr. Hopkinson's address that it should be possible on the Weber hypothesis to get increased permeability in iron by magnetising it first in one direction and then in another at right angles to it, we proceeded to investigate the point as follows:—A ring of inch square Lowmoor iron had a groove turned in it, and a lid made to fit it very accurately.

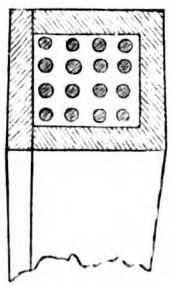

FIG. 1.

The sketch (Fig. 1) shows a section of the ring and coil. Inside the channel thus prepared was laid a coil previously wound on a former with a secondary coil, by means of which the induction produced by it could be measured. We call induction in this direction *transverse* induction. The lid was then fitted on, the ends of the coils coming out through two small holes. Another primary and secondary were then wound on the ring in the usual manner at right angles to the former pair, and producing *longitudinal* induction in the direction of the grain of the iron. The force-induction curve of the iron in each direction was then taken in the usual manner, after all traces of induction at right angles to the direction under investigation had been removed as far as possible by repeatedly putting the iron through the required cycle.

The results of our investigations were as follows:—The curves for longitudinal and transverse induction taken independently in the usual manner are shown in the upper curves in Fig. 2.

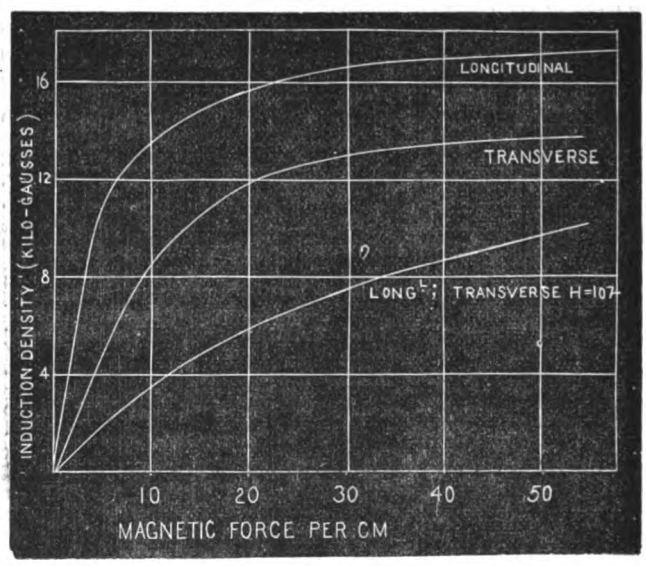

FIG. 2.

The lower values for the transverse induction are presumably partly due to the grain of the iron, and partly to the joint. We then took a longitudinal curve, applying and removing a strong transverse magnetising force between each observation. The result is seen in Fig. 3, which shows how nearly the points obtained after thus "joggling" the iron fall on the ordinary curve. Practically the two curves are identical. A longitudinal curve was then taken, a transverse magnetising force of 100 C.-G.-S. units remaining on all the time. The upper and lower curves on Fig. 2 show the force-induction curves for the longitudinal direction without and with transverse magnetisation. The permeability shows a

Digitized by Google

large decrease, due, of course, to the fact that the plane of the induction alters with each alteration of the transverse magnetisation; and the secondary only measures the *component*, so to speak, of the induction at right angles to itself.

This experiment shows that for such forces as we were dealing with, *no* increase of permeability takes place. And, indeed, after making these experiments and thinking over the matter carefully, the following seemed clear to us:—The iron must be totally unconscious of *two* magnetising forces; it only feels *one* force, due to the resultant of the two, and an induction is produced in that direction, so that if we knew the length of the path of induction, we could probably predict its value.

Why, then, should the component of the induction in the longitudinal direction be greater than it would be if there were no transverse magnetising force? On thinking it over, we could see no reason why it should be, and it was not. The phenomena, however, lay somewhat outside the limit of our researches, and we therefore followed them no further. The above considerations, however, seemed to us common sense; but it is true that no amount of common sense, much less mathematics, appears to enable one to predict what molecules will do under untried circumstances.

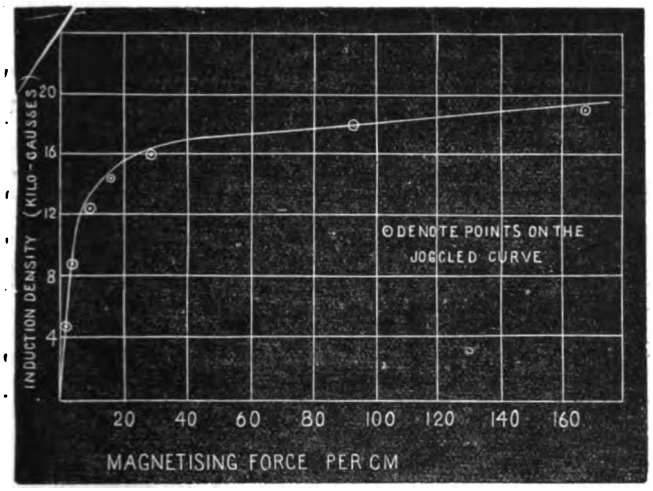

FIG. 3.

It may be noted that while our experiments, as we have already stated in another place, distinctly contradict Prof. Ewing's ideas on instability as far as regards masses of iron of the size used by us—that is to say, no amount of hammering could remove the residual induction—the very smallest magnetising force, applied at right angles to this residual induction, removed it entirely. This property might be utilised to eliminate hysteresis errors in a measuring instrument.

Our results, in short, show, as far as they go (1), That no such increase of permeability, as anticipated by Mr. Swinburne on the Weber hypothesis, actually takes place; and (2), That no increase of permeability in one direction takes place when a constant transverse magnetising force is maintained.

May we, in conclusion, suggest to Mr. Kennelly that his results would be more palatable and more easily comprehensible if they were expressed in curves, as well as in his pages of appalling figures? Apologising for the length of this communication,—Yours, &c.,

SYDNEY EVERSHED,
ERNEST B. VIGNOLES.

Woodfield Works, Harrow-road, W., June 10, 1890.

P.S. The experiments described above have nothing whatever to do with the initial part of the force induction curve for iron, to which so large an amount of attention has been devoted, and which is of so little practical importance.

[Although the magnetising forces in these experiments were at right angles to each other, they were of such magnitude that neither was perpendicular to the induction produced. This can only be the case when, as in Mr. Kennelly's experiments, one of the forces is small compared with the other. In fact, the forces dealt with by Messrs. Evershed and Vignoles were large enough to shift the induction round, making it cross joints and altering its course altogether; and the influence of this alteration was far more important than the alteration of what might be called specific magnetic resistance. We trust that the curves which appear this week will make Mr. Kennelly's results more palatable and comprehensible.—ED. *E.*]

PHOTOGRAPHS OF ELECTRIC DISCHARGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have recently taken several photographs of spark discharges from a Wimshurst machine, and of which I send you four. The length of spark was about 3in., while you observe that of the photographs is about 1½in.; this was as close as I could get the camera to the terminals without the brass work of the lens affecting the working of the machine. The sparks, you will notice, have a very zigzag course, some of them being much thicker at one end than at the other, while that of No. 1 is very thick throughout its length. The dry plates I used for Nos. 1, 2, and 3 (reproduced above) were the Ilford Special Rapid, and for that of No. 4 the ordinary make. Lately I have by means of a 4in. compound condenser thrown the enlarged image of the spark on a screen. The effect is then very brilliant, although the utmost length of spark I could get in the room in which I experimented was 6ft. or 7ft. A curious optical effect occurs in the enlarged image. Immediately the

bright spark ceases on the screen, a black streak appears of exactly the same shape and in the same place as the bright spark, and seems to remain on the screen for a short time, and gradually fade away.—Yours, &c., W. GILLETT.

Slough, Bucks, June 6, 1890.

THE WIRING OF HOUSES FOR THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the article on house-wiring in your last week's issue, there are some remarks therein which may be most unfavourably read in connection with small firms.

Although there are a large number of firms who have taken up the electric lighting business without any previous experience or technical assistance, this is not entirely the case; and it is in the interest of those qualified to do the work that I am now writing. Many of these small firms consist of men who, having had some years with a good and well-known firm, have now commenced business for themselves, and, thanks to careful personal supervision, turn out better work than their larger rivals, who in many cases leave the work in the hands of students and incompetent foremen. It is uphill work starting a new business, and a word from almost anybody will frequently spoil probable business. Only this morning I was told by a shopkeeper, to whom I had quoted a price, that he had been advised that my price was far too low for good work, and he preferred to put the job in the hands of some well-known firm that he could rely upon. (Said adviser has *two* years' electrical experience as against my *eighteen*, nine of which have been with electric light work of all

Digitized by Google

kinds.) Were that man to read the remarks I refer to in your paper, he would doubtless be strengthened in his belief that I was going to give him something cheap and nasty; and yet I will guarantee the quality of all the material quoted for to be above the average for shop work. The workmanship, too, I could guarantee, as I pay wiremen 9d. per hour and keep only the best. Good men are fully worth it. I may also mention that the estimate showed a gross profit on outlay for labour and material of 36½ per cent., which is quite high enough for a well-managed business.

I think, Sir, in the face of the above, it is hard on the small men to be indiscriminately condemned in a leading technical paper such as yours is, although I do not suppose for one moment the remarks were meant in their widest sense. My object in writing is simply to prevent, by your kind assistance, the publication of any similar remarks which may, unintentionally, do harm to trustworthy men.—Yours, &c., A. I. E. E.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

St. Pancras Electric Lighting.—Extension of Time.—It will be seen from our advertisement columns that the time for sending in tenders has been extended from June 23rd to June 30th.

Tenders Invited.—The Town Commissioners of Dundalk invite tenders for lighting the streets of the town by electricity, gas, or oil (gasoline). A contract would be taken for a period of one or more seasons, consisting of ten months (from August 1st to June 1st). Service one hour after sunset to one hour before sunrise. The number of town lamps in present use is 185. Mr. Edward Ferrar, town clerk, Town Hall, Dundalk, will supply all particulars. Tenders will be considered at the meeting of the Commissioners on Wednesday, June 25th.

Tender Accepted.—We understand that the tender of Messrs. Percy Huddleston and Co. has been accepted by the Metropolitan Asylums Board for the electric light cable advertised in our issue of May 23rd, as lying on shore abreast the training ship "Exmouth," off Grays, Essex.

Patent Litigation.—We understand that the Courts will shortly be engaged in settling the rival claims of two manufacturing and supply companies to patents for electrical apparatus, &c. We hope to hear that matters will be arranged without recourse to litigation.

Messrs. Charlesworth, Hall and Co.—We have received from Messrs. Charlesworth, Hall and Co. the newly-issued, neatly-printed sheet "A. N." of price lists of their well-known dynamos. Hall's patent "Oldham" dynamo is illustrated, as well as a steam dynamo for 60 amperes, at 65 volts, at 500 revolutions per minute. Views are also given of a dynamo for 280 amperes; of a dynamo and turbine; of a dynamo arranged to be driven by a gas engine for 150 amperes, at 100 volts, at 670 revolutions per minute; and of a well-made electro-plating dynamo for 1,000 amperes, at 10 volts, at 800 revolutions per minute. The commercial efficiency of these machines is stated to be up to 96 per cent.

Messrs. Blenheim and Co.—We have received from Messrs. Blenheim and Holland a notification that, as announced in our last issue, the partnership carried on at Egham, Surrey, under the style of Messrs. Blenheim and Co., electrical apparatus and telephone manufacturers, has been dissolved by mutual consent. We are further notified that the business will be carried on as usual by Mr. W. Blenheim alone as from May 31st last.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

May 14, 1890.

7,513. W. L. Wise. London. Improvements in the manufacture of electrodes for secondary batteries (P. Schoon, Switzerland).

7,518. A. Walker and T. J. D. Rawlins. London. Improvement in means for preventing polarization in primary batteries.

7,540. W. L. Wise. London. Improvements in electric arc lamps (La Société Japy Frères, France).

May 15, 1890.

7,553. E. F. Furtado. London. Improvements in electro-telephonic apparatus.

7,560. C. R. C. Smyth and E. Payne. Glasgow. Improvements in and connected with ammeters and voltmeters.

7,572. F. Suter. London. Electric sign.

7,581. W. A. Thoms, London. Improvements in the electro deposition of heavy metals and their alloys.

7,599. R. Belfield. London. Improvements in electric arc lamps (P. Lange, United States).

May 16, 1890.

7,618. J. P. Bayly. London. Improved electrical device for use in dental operations (C. W. Manker, United States).

7,619. J. P. Bayly. London. Improved galvanic apparatus for use in dental surgery (C. W. Manker, United States).

7,624. J. A. Kingdon. London. Improvements in electrical transformers.

7,663. E. Fischinger. London. An improved method of and means for distributing electric current in central systems.

7,670. C. D. Abel. London. Electric meter (La Société Anonyme Continentale, France).

7,674. J. A. Jobling. London. Improvements in the manufacture of glass shades for electric lamps.

May 17, 1890.

7,725. C. E. Challis and G. Graham. London. Electric switches.

May 20, 1890.

7,819. G. J. Larner. Darenth, near Dartford, Kent. Timing the arrival of a homing pigeon by electrical means.

7,836. F. Stitzel, C. Weinedel, M. J. Schwartz, A. Reutlinger, J. H. Egelhoff and J. Kreiger. Glasgow. Improvements in electric semaphores for railways.

7,853. W. P. Thompson. Liverpool. Improvements in welding metals electrically, and apparatus therefor (C. L. Coffin, United States).

CITY NOTES, &c.

BELL TELEPHONE COMPANY.—This Company has declared the regular dividend of 3 per cent., with 6 per cent. extra, payable July 15.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended June 6, 1890, amounted to £4,094.

COLUMN PRINTING TELEGRAPH COMPANY (LIMITED).—The prospectus of this Company has been issued this week. The Company has been formed for the purpose of acquiring and working Messrs. Moore and Wright's patent for printing by electric telegraph political and general news, stock lists, racing results, despatches, and bulletins of all kinds. The secretary is Mr. W. P. Forbes, and the offices are at 5, New Bridge-street, Blackfriars, E.C. The list opened on Wednesday, and closes to-day (Friday) at 4 p.m. The capital of the Company is £100,000, and the present issue is for 50,000 shares of £1 each, of which 10,000 have been reserved as part payment for the vendor, and 40,000 are now offered for subscription, payable 5s. on application, 10s. on allotment, and the remainder in instalments, if required, at intervals of not less than twelve months.

EXCHANGE TELEGRAPH COMPANY (LIMITED).—With reference to the prospectus noted above, the Exchange Telegraph Company (Limited) state that they are prepared now, as in 1882, to supply column printing telegraph instruments for the diffusion of news, and add that the statement contained in the prospectus that the Moore and Wright machine is unsurpassed in speed is inaccurate, the speed, as taken by competent observers, being much less than that of the column printer of the Exchange Telegraph Company. The type of Messrs. Moore and Wright's machine is also smaller. Another statement in the prospectus is that there are over 1,000 type-printing telegraph instruments in use in London; the Exchange Telegraph Company also contest this point, and add that the field for the employment of telegraphic type-printing instruments is limited.

NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY.—The first annual meeting of shareholders was held last week. The Directors' report stated that the site in Angel-lane had been secured at a net cost of £810, after selling off some of the frontage to the Corporation. Contracts had been entered into with Messrs. Green Brothers for erecting the necessary buildings and laying the mains; and orders for engines and dynamos, representing an expenditure of some £5,000, had been given. The report, which spoke hopefully of the prospects of the Company, and acknowledged the indefatigable services of Mr. Montague Browne, the secretary of the Company, was adopted.

POOLE AND WHITE (LIMITED).—The statutory meeting of this Company will be held at the offices, Bread-street, E.C., this day (Friday) at 12 o'clock.

SOCIETE GENERALE DES TELEPHONES.—The general meeting of this Company will be held on the 18th inst., when a dividend of 25 francs per share will be announced. The profits from the manufacturing business alone amounted, during the past year, to 1,680,000 francs, of which 600,000 francs will be carried to the reserve fund.

THE DEVELOPMENT OF ELECTRIC TRACTION.—We hear that a new company will shortly be brought out with a million capital for the development of electric traction on the Thomson-Houston and Series systems. Contracts are said to have been entered into to the extent of about three-quarters of a million for equipping tramways in various parts of the country, and experiments will also be made on the Metropolitan District Railway between Acton and Hounslow.

UNITED RIVER PLATE TELEPHONE COMPANY (LIMITED).—Notice is given that the transfer books of the Five per Cent. Debenture Stock of this Company will be closed from the 16th to the 30th inst., both days inclusive, for the purpose of preparing the half-yearly interest warrants.

WESTERN UNION TELEGRAPH COMPANY.—The Directors of this Company have declared a quarterly dividend of 1¼ per cent.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended June 6, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,143.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

JABLOCHKOFF'S **DISTRIBUTION PATENT**

(BEING A PATENT FOR "PRODUCING AND DIVIDING ELECTRIC LIGHT," No. 1996 of 1877.)

THE ELECTRICAL ENGINEERING CORPORATION, LIMITED

(STATTER'S) Are Proprietors of the above Patent, and Warn the Public against Infringement. (UNITED).

The following are Licensees:—

Brush Electrical Engineering Company, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
M. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.

3, PRINCE'S MANSIONS, VICTORIA STREET, WESTMINSTER.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL O

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 631.—Vol. XXV. FRIDAY, JUNE 20, 1890. Price Fourpence.

NOTES.

The exhibits of the Royal Society's second *soirée* were in many cases the same as those shown on May 14th. Prof. Thompson showed Kœnig's experiments on beats and beat tones; and amongst the new exhibits were some photographs of lightning flashes, shown by the Royal Meteorological Society, and some interesting photographs of musical sparks by Sir A. C. Campbell. Two Hughes' telegraphs were shown working direct to Berlin, Paris, and Rome. Among the most interesting features of the evening were Dr. Fleming's electro-magnetic repulsion experiments, several of the most striking of which had not been shown before. One of the new Thomson alternate-current motors was seen in action, being driven by a transformer fed from the neighbouring circuit. As is well known, this motor is started by rectifying the currents through the armature by a commutator and brushes; but when synchronism is attained the armature is automatically short-circuited, and the brushes may be removed.

The Electrical Trades' Committee was occupied at its last meeting with matters of considerable commercial importance; and, as usual, the actions of the Board of Trade and of the Local Authorities were the subjects discussed. That the neat-looking Rule 9 of the Board of Trade's regulations with regard to the insulation of overhead wires should have resulted in converting electrical cables into "puddings," is an example of the danger of drawing up rules without taking the trouble to see what they lead to; and the announcement made by Mr. Garcké that Local Authorities to whom concessions have been given are seeking to impose onerous if not impossible conditions upon contractors desirous of undertaking the actual work, is but the logical consequence of granting these bodies so many privileges. No doubt, as a relief to these somewhat sombre topics the Committee, as will be seen by our Notes column, devoted the remainder of its time to the organisation of a river excursion. A quiet run up the Thames in an electric launch will perhaps prove a pleasant relief from unworkable Board of Trade rules and regulations and the exactions of Local Authorities.

On more than one occasion we have alluded to experiments undertaken with the view of determining whether the passage of an electric current between the wheels of a car and the rails does or does not increase the adhesion between them; the general result of these experiments tending to show that, unless the currents used are stronger than those generally employed on electric railways, no such effect takes place. We publish this week an account of the work of Mr. Ries, who claims to have been the first to call attention to this matter. His experiments have been carried out in a much more satisfactory manner than any we have yet noticed. The current used with the idea of increasing the traction was generated for that purpose only, so that by suddenly switching it on or off its effect could be with certainty detected; and as some of the experiments were made on an engine weighing 50 tons, used to draw a train of a dozen loaded coal waggons with the brakes in action, the practical magnitude of the forces dealt with is sufficiently indicated. The increase of over 25 per cent. in the tractive adhesion, found in such experiments, is to be accounted for by the heating effect at the surface of contact, caused by the passage of the current, this being of sufficient magnitude to produce an instantaneous weld. The currents required are much larger than those employed in common systems of electric traction; but the energy required to generate them is stated to be small compared with that needed for locomotive purposes, so that a new and highly promising application of electricity is disclosed. The current used as a traction increaser is generated quite independently of any used for motive power, and it is evident that the discovery may be adapted to all locomotive cars and need not wait for the development of electric traction for its application. It is satisfactory to note that extensive experiments are to be carried out under conditions which will thoroughly test the capabilities of the method. The discovery will be of comparatively little use unless applicable when the speed of the locomotive is fairly high; and for this reason special attention should be directed to the connection between the current density required and the velocity of the train.

In a short but instructive Paper, which will be found in another column, Lieut. Wilkes, of the United States Navy, usefully points out what a great field modern navies offer to the most important branches of applied electricity. The electric light has long ago become indispensable to every man-of-war; and at the present moment both electric power and electric welding are being tentatively introduced on board ship. Naval yards are, moreover, a close approximation to the ideal as places in which to distribute current for the purposes of light and power. A dockyard central station has a compact area to deal with, and current is required both for street and house lighting, stationary motors, and electric welders; and probably, in

Digitized by Google

the near future, electric traction will come into general use for the transportation of naval material from place to place within the yard.

THE eight requisites of a good marine dynamo detailed by Lieut. WILKES might, with little alteration, be made applicable to dynamos working in many of our London central stations, in which the underground situation renders compactness, cool running, and ability to dispense with frequent examination as important as in the case of a machine placed in the engine-room of an ironclad. The two main features which should distinguish a good marine dynamo from one intended for ordinary land service are, of course, freedom from liability to injury by salt water and complete absence of stray field. Neither of these desiderata would appear as yet to have been altogether satisfactorily fulfilled across the Atlantic.

A REMARKABLE effect of electric oscillations has been recently pointed out by Prof. MINCHIN in the columns of our contemporary, *Nature*. Two metal plates attached to platinum wires are sealed in a closed glass vessel containing alcohol. One of these plates has been previously sensitised by some process not described; and it is found that, if light falls upon this its potential differs from that of the second plate by more than half a volt, and may be detected by an electrometer. A slight tap will, however, render the cell insensitive to light; a second tap will restore the sensitive condition, and so on, the two states occurring alternately, and being indicated by the movements of the needle to and from the zero position. The influence of an electric spark on such a cell is still more remarkable. If the cell is in the insensitive condition, the sensitive state can be at once restored by simply causing a spark to pass between the terminals of a Wimshurst machine or of a Hertz oscillator. The effect takes place even if the spark is caused at a distance of many feet from the cell. Prof. MINCHIN explains the effects by assuming that the molecular state of the surface is altered, and assumes that light energy can be taken up electrically for one condition but not for the other. If this is so, there are probably many other instances in Nature; and thunderstorms and other electro-magnetic disturbances may considerably influence the manner in which the energy of sunlight is taken up by plants or utilised in other ways.

THE Patton Motor Manufacturing Company of Chicago has devised a system of electric traction distinctively its own. The basis of operation, we are told, is the "generation of electricity upon the vehicle, thus rendering each car independent and dispensing with overhead or conduit wires for the transmission of electric force." The "generation of electricity upon the vehicle" is effected by installing a gas engine and dynamo upon a separate car, the current from the dynamo when not employed in supplying the motor, charging a battery of accumulators arranged under the seats of the passenger car, "so that reserve force is always in readiness for any emergency." This idea reminds us of the ingenious proposal put forward some twelve months ago on the other side of the Channel, that each gas lamp should be surmounted by an arc light supplied with current from a dynamo driven by a small gas engine arranged in the base.

Junior Engineering Society.—Prof. John Tyndall, F.R.S., has accepted the position of vice-president of this society.

Lightning in Italy.—The number of deaths in Italy from lightning during recent years are as follows:—In 1883, 98; 1884, 201; 1885, 182; 1886, 137; 1887, 260.

The Lighting of the Eiffel Tower Lifts.—The lifts at the Eiffel Tower are now lighted by the electric light, the current for the lamps being obtained from a Renard battery.

Llanelly.—The Local Board have granted permission to the Llanelly Electric Light and Power Company to apply to the Board of Trade for a licence to supply certain districts of the town with electricity.

Electric Traction at Birmingham.—A trial was made on Wednesday evening last week of one of the accumulator cars about to be introduced on the Bristol-road line of the Central Tramways Company's system.

Berthoud-Borel Cables.—The latest type of Berthoud-Borel cable is insulated with layers of celluloid tape, over which a layer of hemp is wound, the whole being then plunged into a bath of hot liquid insulating compound.

The London County Council and Overhead Wires.—On Friday last the Select Committee of the House of Commons, presided over by Sir Joseph Bailey, passed the Bill promoted by the London County Council for regulating overhead wires.

A New Text Book.—We are pleased to see, from a note in the *Electrical Engineer* of New York, that Dr. Fleming's "Alternate-Current Transformer" (Vol. I.) has been adopted as a text-book in Physics IV. (Electrodynamics) at Harvard University.

The Central London Railway Bill.—The Corporation will oppose this Bill in the House of Lords in order to prevent the mutilation of the clauses which have been inserted by the Select Committee of the House of Commons for the protection of the City.

Society of Arts.—We are glad to note that the Society of Arts has awarded its silver medal to Dr. J. A. Fleming, for his excellent Paper on "Prof. Elihu Thomson's Electro-Magnetic Induction Experiments," which appeared in these columns a few weeks ago.

The Halifax-Bermuda Cable.—The "Westmeath," with the Halifax and Bermuda cable on board, arrived off Bermuda on the 7th inst., and, having completed the necessary soundings, proceeded to Halifax, which port she reached on the 16th inst., and will at once commence to lay the cable.

The Royal Military Tournament.—At the Royal Military Tournament this year the armour-plated train with Gatling gun is drawn by a self-contained electro-locomotive, constructed by the Electric Construction Corporation. The use of electricity in this connection will be watched with interest.

Gevelsberg.—From the *Elektrotechnisches Echo* we learn that the town of Gevelsberg, Westphalia, a place of about 10,000 inhabitants, will be lighted by electricity from the end of September. The Tudor accumulator is to be used, and 1,500 lamps will be put up at first, the number being afterwards increased to 4,000.

The Lane Fox Patents.—The following are the royalties which the Lane Fox Electrical Company has finally decided to demand from the owners of private installations:—Private houses—1s. 6d. per 16 candle-power lamp, per annum; other installations—such as hotels, clubs and offices—2s. 6d. per 16 candle-power lamp, per annum.

Thunderstorms.—During a heavy thunderstorm at Lewes, on Thursday last week, a man was killed by lightning. At West Bromwich the wires connected with the telephonic apparatus at the Central Fire Station were struck by lightning. Several of the wires were melted, and communication with seven of the places connected was rendered impossible.

Swansea.—The work of lighting the whole of the Swansea Harbour Estate by electricity has just been completed. The previous installation had comprised merely the Prince of Wales Dock and the pier; but the trustees, finding the system worked well under the present management, resolved to light the whole estate. The work is of a thoroughly satisfactory character.

Digitized by Google

Tory Island Lighthouse.—In answer to a question put in the House of Commons last week, Sir M. Hicks-Beach stated that the contract for the manufacture and laying of a cable connecting this island with the mainland would be signed in the course of a few days, and also the contract for the erection of the necessary buildings. It was believed that the signal station would be in working order within a few weeks.

Institution of Electrical Engineers.—We understand that the President was desirous of rendering the annual *conversazione* especially attractive, and with that view intended to have held it in a new *locale*. Every preparation had been made for this; but, unfortunately, at the last moment, the arrangement fell through. As it is now too late in the season to make any other arrangements, the *soirée* will be postponed until after the recess.

The Telegraph Clerks' Grievances.—In answer to a question by Earl Compton, with regard to the telegraph clerks' grievances, the Postmaster-General stated on Friday last that the Departmental Committee appointed in March had presented their report, and he hoped to be able to announce the decision of the Government at no distant date. One important change relating to sick pay was, he stated, carried into effect on June 1st.

The Australian Transcontinental Telegraph Line.—During 1888 the telegraph line connecting Port Darwin and Adelaide was interrupted eight times. Lightning and floods were responsible for most of these interruptions, which were all of brief duration; one, however, was due to three posts and twenty miles of wire having been stolen. On another occasion a wandering European cut the wire in order to bring the linemen to his rescue.

Burton-upon-Trent.—The Corporation, having been granted a Provisional Order, have issued a circular with a view of obtaining an idea of the probable quantity of electrical energy which will be required by private consumers. The maximum price allowed in Burton is eightpence per unit, and if the demand is limited that is the rate at which the Corporation propose to charge until they have obtained some experience as to the cost of production.

Technical Instruction.—The Lords of the Committee of Council on Education have decided, with the sanction of the Lords Commissioners of Her Majesty's Treasury, to allocate a fixed sum each year in the vote for the Science and Art Department for grants in aid of technical instruction given under the Technical Instruction Act, 1889, or under the Technical Schools (Scotland) Act, 1887. The sum so allocated for the financial year 1891-92 will be £5,000.

Agra.—There is every hope, says the *Indian Engineer*, that within the space of two months the Taj will be permanently lit up with the electric light. It is proposed to place 1,200 candle-power lights on each of the front minarets, and 1,000 candle-power lights on each of the back minarets and on the Musjid and Jawab. The main building will have no light stationed upon it, and so will be magnificently thrown into relief. The expense has been computed at Rs. 12,000.

Telephonic Contracts.—In the action Mordey, Carney and Co. *v.* Jacobs and Co., heard recently before the Newport County Court, the counsel for the defence submitted that there had been an unfortunate mistake. The negotiations, which related to a contract for towing a barque from London to Newport, were conducted by telephone, and the individual at the defendants' end of the line was hard of hearing occasionally, and the telephone was indistinct. These circumstances caused the misunderstanding. The Judge, however, gave judgment for the plaintiffs.

New Anglo-Scandinavian Cables.—The Great Northern Telegraph Company is contemplating laying down one or two new telegraph cables between Scandinavia and England. A cable will be laid between Gothenburg, on the Swedish side of the North Sea, and Newcastle-on-Tyne on the other side. This will be the first direct cable between Sweden and England. This new cable is expected to bring about a material increase in the Swedish telegraphic intercourse, as a large number of telegrams are likely to be sent by the new line from Russia and Northern Asia to England.

Obituary.—The death is reported of Mr. Thomas Brown Jordan at the age of 82. Mr. Jordan was born in Bristol in 1807, and established himself in Falmouth as a mathematical instrument maker, and effected improvements in the dipping needle and the miners' dial. About 1838 Mr. Jordan invented a declination magnetograph and a self-recording actinometer. From 1840 to 1845 Mr. Jordan held the appointment of first keeper of mining records. During this period he devoted considerable time to electro-metallurgy. He finally established himself in London as a mining and mechanical engineer in conjunction with his two sons.

A Remarkable Short-Circuit.—The *Electrical World* gives the following account of a peculiar accident that happened to the East Liverpool, Ohio, Western Electric Company a short time ago. The switchboard caught fire, the machine began "flashing," and the lights went out. Upon examination, it was found that an ordinary card photograph had by some means fallen into the switchboard, and the gilt edge around it had come in contact with the two ends of the line, causing a short circuit. The wires were separated from the switchboard, united temporarily with connectors, and everything was started up again with a stoppage of only a few minutes.

Barnsley.—At the last meeting of the Town Council, the Park and Lighting Committee reported that Mr. Bromley Holmes had given them information as to the tenders for an electric lighting plant. They also reported that the Barnsley Gas Company were ready to enter into a contract with the Council for lighting the street lamps in the borough; and as the terms were substantially those agreed to by the Council, the committee recommended them for acceptance, subject to six months' notice. A long conversation followed, and the report was eventually approved, it being stated that the final report of the committee on the electric lighting question would be in the hands of members a week before the next Council meeting.

The Tower Competition.—After careful consideration the Committee appointed to consider the designs for the proposed tower have awarded the prizes as follows:—First prize, 500 guineas, to Messrs. A. D. Stewart, J. M. McLaren, W. Dunn, 21, King William-street, Strand, W.C., joint authors of design No. 37. Second prize, 250 guineas, to Messrs. J. J. Webster and T. W. Haigh, 67, Lord-street, Liverpool, joint authors of design No. 51. The Committee consider the design No. 50, by Mr. Max am-Ende, deserves honourable mention. The Committee consisted of Mr. E. H. Carbutt (Chairman), Sir Frederick Bramwell, Sir Benjamin Baker, Sir E. J. Harland; Prof. Alex. B. W. Kennedy; Messrs. C. Liddell, J. F. Moulton, and Thomas Verity.

The Edison Lamp Patents in Germany.—The lawsuit brought by the German Edison Company against Messrs. Naglo, of Berlin, to which we referred in our issue of May 23rd, and which was decided in the favour of Messrs. Naglo, was chiefly noteworthy for a decisive report of Prof. Kohlrausch. In his report Prof. Kohlrausch stated that it was impossible to make an incandescent lamp according to the Edison patents of 1879, and that it was not until after the publication of Swan's patents that a practical incandescent lamp could be manufactured. Moreover, the report says that lamps similar to those of Edison existed before the granting of the 1879 patents, and that a filament of carbon being thinner or thicker could not form the basis of a patent.

Wimbledon.—A crowded meeting was held last week at the Drill Hall, Wimbledon, for the purpose of ascertaining the opinions of owners and ratepayers with regard to the scheme of the Local Board for lighting the town by electricity. Mr. Arthur Holland, chairman of the Electric Light Committee, gave an explanation of how the Board proposed to carry out their scheme. Several questions concerning the scheme were asked from the body of the hall, and replied to by Mr. Preece and Mr. Holland; but the answers failed to give satisfaction, in spite of the repeated declarations of the chairman that the meeting was not a public one. A resolution against the scheme of the Local Board was carried by a large majority, and the meeting broke up in confusion.

London County Council and the Board of Trade Regulations.—At the meeting of the London County Council last

Digitized by Google

week the Highways Committee reported that they had had before them a letter from the Board of Trade, forwarding certain regulations for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy which the Board proposed to issue under the Electric Lighting Acts, 1882 and 1888, and asking for any observations which the Council might have to make with reference thereto. The Committee stated that, having carefully considered the proposed regulations, they had directed a letter to be sent to the Board, offering suggestions for some amendments which it appeared desirable should be made.

The Duplication of Telegraphic Communication with Australia.—On Friday last Sir G. Baden-Powell asked the Under-Secretary for the Colonies whether any definite proposal had been recently brought to the notice of the Colonial Office for duplicating telegraphic communication with Australia by means of a cable connecting with the African system, and touching at Mauritius; and whether Her Majesty's Government would view with favour such alternative communication, as being of great commercial and strategic value. Baron H. de Worms said that the answer to the first portion of the question must be in the negative. In reply to the latter portion he was sure that Her Majesty's Government would be glad to see such a line of telegraphic communication established.

A Correction.—Our attention has been called to an error in the table on the top of p. 71 of our issue of May 23rd. The order of the last two columns should be as follows, commencing at the tenth line:—

Mean sphr. C.P. per E.H.P.	Mean hor. C.P. per E.H.P.
159	184
179	203
210	244
141	177
157	191
185	217

The table occurs in Mr. Puffer's valuable Paper on incandescent lamp testing, which we abstracted from the *Electrical Engineer* of New York.

Bolton.—Messrs. Dobson and Barlow, of Bolton, have placed 650 incandescents in a portion of their extensive machine works. Should the electric light be ultimately adopted throughout the works, about 4,000 lights will be required. The shop, which has been fitted with the electric light, used to be almost unbearable from the heat and fumes of the gas, and since the adoption of electricity the average number of men on the sick list has been reduced. The electric light is also being adopted in the large printing works of Messrs. Tillotson and Son. It is likely that electricity will be adopted in the new North End Mill, one of the largest now being erected in Lancashire. The master drapers of Bolton are also agitating for a combination for supplying themselves with the light.

City of London and Southwark Subway Bill.—A Select Committee of the House of Lords, on Tuesday last, presided over by Lord Belper, passed this Bill. The Bill, it will be remembered, has already been sanctioned by the House of Commons, and authorizes the City of London and Southwark Subway Company to extend their line from its present terminus at Stockwell to Clapham Common. For the purpose of carrying out this extension of about one mile, the Company are empowered to raise £200,000 additional capital, and to borrow in respect of that capital the sum of £50,000. The name of the Company is changed into the "City and South of London Railway Company," and an extension of time is granted within which to complete the construction of the original line.

The Profits of the Paris Exhibition.—M. A. Neymarck has recently made a communication to the *Chambre Syndicale des Industries Diverses* of France, on the subject of the profits of the late Exhibition to France in general. Adding together the increase of the bank balances, of the receipts of railroads, of the revenue, &c., a total gain not far short of five hundred millions of francs is made out. To this must be added the strictly private receipts. Allowing one million and a-half of foreign visitors spending an average of 500 francs each, and six millions from the provinces of France spending an average of about 100 francs each, 1,250 millions appear as the private receipts, giving a total of 1,750 millions of francs direct monetary gain. The figure of £70,000,000 thus arrived at requires, however, close investigation before it can be generally accepted.

The Australian Cable Rates.—Mr. Jackson stated in the House of Commons on Thursday evening last week that it was a fact that the principal Australian Governments had made a proposal that the Imperial Government should join in the payment of a subsidy to cable companies, and also in the guarantee against loss on the proposed reduction of the rates by one-half; but that the Government had not acceded to the proposal.—A Melbourne cablegram, dated June 16, states that the Australian Governments, not being satisfied with the decision arrived at by the Imperial Government not to join the Colonies in bearing a certain proportion of the subsidies and guarantees to the cable companies, the Agents-General have been instructed to make further representations on the subject, with the object of inducing Her Majesty's Government to reconsider their decision in the matter.

Observations on Atmospheric Electricity in the Tropics.—In order to investigate the relations of atmospheric electricity to the moisture of the air within certain limits, Herr F. Exner has made observations of the fall of atmospheric potential in countries with high relative moisture, particularly in the Indian Ocean between Aden and Bombay, in Bombay itself, and in Ceylon both on the coast and in the interior. The measurements were made with transportable apparatus invented by Herr Exner. All the values of the fall of potential were positive. Near the coast the finely-divided spray arising from the breaking of the waves exerted an increased action on the fall of potential. On the other hand, measurements made in Cairo and the vicinity showed that there the dust of the air exerted a lessening influence on the fall of potential, which with a strong wind was so marked that the sign of the fall of potential became negative.

Electrical Trades' Section River Excursion.—At the last meeting of the Electrical Trades Section of the London Chamber of Commerce, it was proposed that the members of the Section should have an excursion on the river on Saturday, July 5th. Members who intend to be present should notify the same to Mr. A. P. Trotter, 28, Victoria-street, S.W., so that the necessary arrangements may be made. Members may bring friends (ladies or gentlemen), but no member can have more than four tickets, including his own. The price of the tickets (not including wine) cannot be definitely settled until it is known how many will be taken; but it will not exceed 12s., and if a fair number join this figure will of course be reduced. The list will close on Monday next, 23rd inst., at 10 a.m. The party will probably embark at about noon, thus allowing members time to open letters, &c., before starting. Members who desire to return early will be enabled to do so by train from some point up the river.

Manual Instruction.—With a view to develope this instruction in a practical direction, and to assist and encourage the formation of classes for manual instruction, grants will be made by the Department of Science and Art towards the maintenance of such classes in connection with elementary schools teaching drawing, or in connection with organised science schools under section 27 of the Science and Art Directory. The instruction must be in the use of the ordinary tools used in handicrafts in wood or iron, and the work must be from drawings to scale previously made by the students. The instruction may be given by one of the regular teachers of the school if he is sufficiently qualified; if not, he must be assisted by a skilled artisan. The work of the class will be examined by the local inspector of the Department, accompanied, if necessary, by an artisan expert on the occasion of his visit to examine the drawing. If it appears that the school is properly provided with plant for instruction, and that the teaching is fairly good, a grant of 6s., or if excellent, of 7s., will be made for every scholar instructed, provided certain conditions have been fulfilled.

The Quantity of Electricity in a Lightning Flash.—Assuming that a normal flash melts a copper conductor of 5 sq. mm. section, Prof. Kohlrausch proceeds to calculate the quantity of electricity involved. A metre of wire of this size weighs about

Digitized by Google

44·5 grammes, and 6,700 calories are required to raise it to the fusing point of 1,200° C. A conductor of 5 sq. mm. section and 1 metre in length has an average resistance of ·01 Ω between 0° and 1,200°. A current C in time t will therefore develop in it

$$\cdot 24\ C^2 \times t \times \cdot 01 \text{ calories.}$$

Now it may be assumed that t varies between ·001 and ·03. Assuming the quantity of heat to be 6,700 calories, we get for C 52,000 and 9,200 respectively for the two values of t. The quantity of electricity would therefore be 52, or 270 coulombs, and would be sufficient to decompose 5 and 25 mgr. of water respectively. Or, taking another illustration, if the quantity of electricity could be stored and used to supply a 16 candle-power incandescent lamp, 35 and 7 of the flashes respectively would be required per hour. Palaz's investigations gave for a flash 28 coulombs.

The Telegraphs of Victoria.—The digest of the statistics of the Colony of Victoria for 1888, compiled by Mr. H. H. Hayter, the Government statistician, has recently been presented to Parliament; and it is there stated that telegraphic communication exists between 601 stations within the borders of Victoria. During the year 1888 the telegraph stations were increased by 86, the lines were extended by 79 miles, and the number of telegrams transmitted showed an increase of more than 20 per cent. over the previous year. A comparison of the two years is made by a table in the digest, giving the number of stations, lengths of line, and amount of business done, which were as follows:—

Year.	Number of stations.	Number of miles of line.	Number of telegraphs.		
			Paid.	Unpaid.	Total.
1888	601	4,194	2,653,000	90,938	2,743,938
1887	515	4,115	2,176,915	83,565	2,260,480
Inc.	86	79	476,085	7,373	484,458

In addition there were 231 miles of line in use as private wires and telephone lines.

An Electro-Pneumatic Railway Signalling System.—An automatic block system has recently been introduced on the Central Railroad of New Jersey, between Jersey City and Bergen Point. In the system adopted the signal arms are moved by the piston-rod of a single-acting pneumatic cylinder, the valves of which are controlled by an electric current. The arm is weighted to fly to "danger" if anything goes wrong with the apparatus. As a train enters a block it cuts the current off from the electro magnets operating the valves of the cylinders of both home and distant signals, which are accordingly both raised to the "danger" position. As the train passes into the next block the current round the distant signal magnet is re-established, and this signal then falls. The home signal, however, remains at "danger" until the train enters the next block but one, when it is lowered in the same way. These operations are carried out in the following way: The rails for one block are insulated from the rails in the preceding and following blocks, and the right and left-hand rails at the commencement are connected with the poles of a two-cell gravity battery. Between the other ends of the rails is inserted a relay, the armature of which, when no train is in the block, is held down by the current from the battery, and completes the circuit of the battery working the semaphore valves. As soon as the train enters the block it short-circuits the relay, which in turn interrupts the current, the semaphore circuit is broken, and the valves of the signals, being no longer held down, they move over, and the signals at the commencement of the block fly to "danger." As the train leaves the block the current is re-established through the relay, and the distant signal falls to "line clear." The home signal is, however, arranged to remain at "danger" till the train reaches the next block, when it is lowered in its turn. This system has been worked out by the Westinghouse Company.

The Kousmine Diffusion Battery.—The diffusion battery of M. Kousmine, which was shown at the recent Galvano-Plastic Exhibition at St. Petersburg, has been much used in Russia. By making use of the phenomenon of diffusion M. Kousmine has succeeded in overcoming the increase in internal resistance of the bichromate of potash battery due to the formation of crystals on the positive electrode. The positive carbon electrode consists of four strips attached to the lid of the battery. The negative zinc electrode consists of a circular grating, resting on the bottom of the battery. By means of a funnel a 15deg. Beaumé solution of sulphuric acid is introduced, until it just reaches the lower end of the carbon strips. A 6 to 7 per cent. solution of bichromate of potash is next introduced. The two liquids do not mix on account of the great difference in their densities. When the battery is short-circuited it is easy to see that chemical action only takes place close to the lower end of the carbon strips, which are gradually surrounded by a violet ring 2 or 3 millimetres deep. Above this region the bichromate solution retains its original colour. The bichromate solution being very weak, the chromic crystals dissolve as soon as they are formed, and the positive electrode is not covered by a deposit as in other batteries. The solution of these crystals, having a greater density than the surrounding liquid, falls to the bottom. The sulphate of zinc also falls to the bottom of the cell, causing more sulphuric acid to rise, A cell having the following dimensions was tested by a committee of experts at the Exhibition in question.:—Height 20 cms., diameter 15 cms., surface of zinc 176 sq. cms., bichromate solution 6 per cent., sulphuricacid 15deg. Baumé. The committee reported that after having been circuited for 8½ hours on an external resistance of ·32 ohms, and then left on open circuit for 10½ hours, the cell continued to work for 4½ hours, when the circuit was again closed, and that it gave during 13 hours 36 ampere-hours for an expenditure of 48 grammes of zinc.

The Epstein Method of Forming Storage Battery Plates.—The object aimed at in this method is to form the plates of a storage cell with greater rapidity than hitherto, without diminishing their durability or capacity. Lead plates of any shape suitable for use as electrodes are put into water rendered acidulated by the addition of about 1 per cent. of nitric acid. The plates are kept from coming in contact with each other, and the water is always kept up to the boiling point, the boiling being continued till the lead has assumed a dull grey appearance. The plates are then taken out of the water and dried in the air. This treatment produces a greyish yellow deposit of lead compounds which has the appearance of mildew. This deposit adheres very firmly, and is insoluble in the electrolyte used for the subsequent treatment in dilute sulphuric acid. In addition it has a great capacity for taking up the gases engendered in the formation process, so that the latter may proceed quickly, without the necessity of reversing the current. It is these "raw" plates, as they are called, from which the positives as well as the negatives are formed. In order to form positive electrodes a number of raw electrodes forming a group are put into the electrolyte, together with positive electrodes, that have to be transformed into negative electrodes. The raw electrodes that have to be formed into positive electrodes are then connected with the positive pole, and the intervening plates with the negative pole of a dynamo or battery. In the process of forming positive electrodes, the former greyish-yellow colour of the raw electrodes changes into a deep dark-brown, almost bluish-black hue, and the process is completed as soon as the electrodes have assumed that colour, and an abundant development of oxygen takes place. The oxygen of the peroxide of lead produced on the positive electrodes which are to be reduced to negatives is absorbed by the effect of the electric current, and the bodies are reduced on their surface to porous metallic lead. The process of forming negative electrodes is finished when the deep dark-brown or bluish-black colour of the positive electrodes used for the purpose has changed into a bluish-grey hue and an abundant development of hydrogen takes place. A few hours only are necessary to form a plate by this method, and the reversing of the current is unnecessary, so that in a very short space of time a great number of positive as well as of negative electrodes can be produced.

MAGNETISM IN IRON AND OTHER METALS.*—XX.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 84.*)

§ 82. Dissipation of Energy by Reversals of Moderately Strong Magnetisation.—When the intensity of magnetisation at which reversal takes place is reduced, the energy dissipated is, of course, less than has been stated in § 81. Fig. 50 shows the effect of subjecting a piece of soft annealed iron wire to a graded series of reversals beginning with weak forces, and gradually increasing the force till the limits of H were ±75 C.-G.-S.† Parts of the curves relating to strong forces are

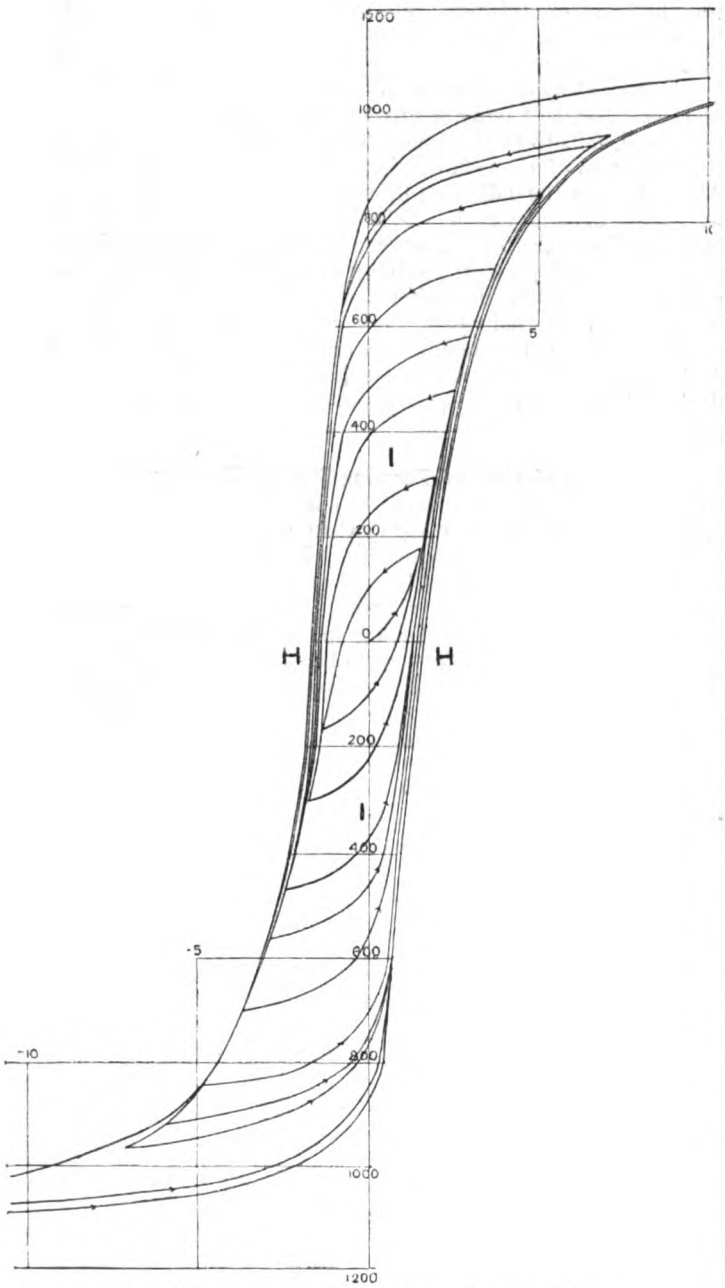

FIG. 50.—Graded cyclical magnetisations of soft iron.

omitted in the figure. The wire was 0·078cm. in diameter and 29cm. long, and was tested by the direct magnetometric method; between 300 and 400 observations of the relation of H to I were required to define the curves in the 10 successive processes of double reversal which are represented in the figure. In Table V. the numbers in the first, second and third column are the values of H, of B, and of I, between which the successive double reversals took place; the next column gives the energy dissipated per cycle in ergs per cubic centimetre, found by measuring the areas enclosed within the curves, and the last shows the rise of temperature which a complete cycle should produce.

These results are shown in Fig. 51 by plotting the measured values of $\int H\,dI$ in terms of the induction, B, at which each double reversal took place. It will be seen from the curve that the waste of energy increases rapidly as B is raised, which is a reason for avoiding high induction in the cores of transformers, and in the armatures of alternate-current dynamos. With low intensities of magnetism the waste is less than proportionally small. Table VI. gives numerical values taken from the curve of Fig. 51, along with the horse-power wasted per ton of iron, if 100 cycles (that is, 200 separate reversals) are completed per second.*

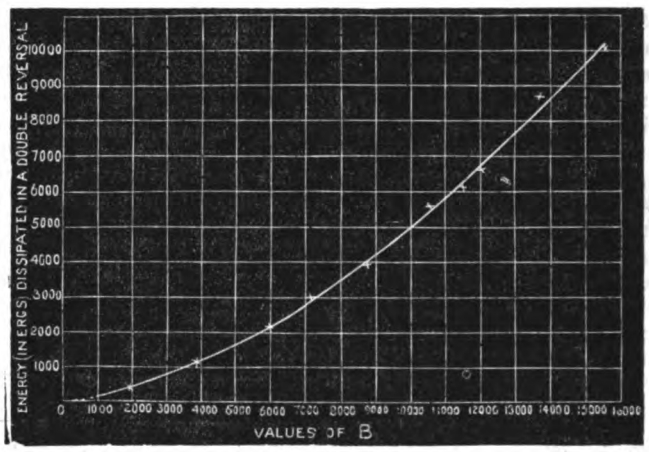

FIG. 51.—Dissipation of energy in soft iron through magnetic hysteresis in double reversals of magnetisation.

Digitized by Google

Fig. 52* shows the results of a corresponding experiment made with a specimen of annealed pianoforte steel wire. Here much the same features present themselves. When the magnetisation is feeble there is but little dissipation of energy, but as the range of I is extended the area of the loops increases fast.

Fig. 53† exhibits, in a different way, the results of these two experiments on iron and steel. The heating effect of a cycle (calculated from $\int H\,dI$) is shown in relation to the value of H which was reversed. At first the heating effect of reversal is much less in steel than in iron, with a given value of H, for its smaller susceptibility makes the whole magnetic change comparatively small in steel. But with stronger fields its greater coercive force begins to tell, and the heating effect becomes at last very much greater in steel than in iron.

§ 83. **Influence of Speed on Magnetic Hysteresis.**—Experiments are wanting to show whether the speed at which a cycle of magnetisation is performed has, in general, any material effect on the value of $\int H\,dI$. In certain cases speed is known to have an effect. In the next chapter results will be described which show that when bars of soft iron are subjected to a very small cyclic changes of H the corresponding magnetic changes depends very largely upon the speed at which H is varied. There does not appear to be anything like so serious a dependance on speed when the magnetic changes are considerable; but it is still doubtful to what extent the results given above, calculated as they

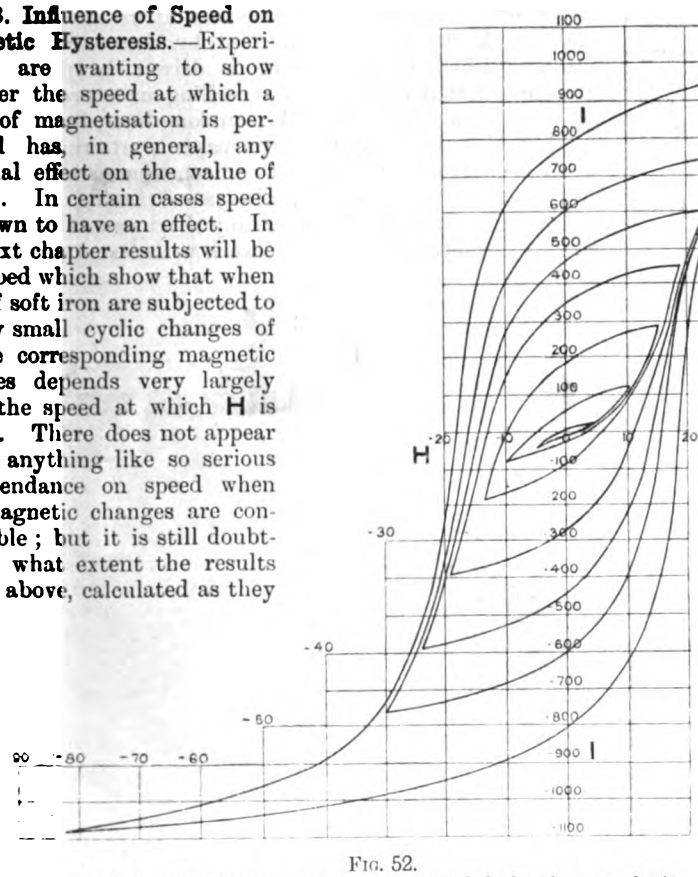

Fig. 52.
Graded cyclical magnetisations of an annealed pianoforte steel wire.

are from the observed relation of I to H when H is changed very slowly, are applicable when H is changed fast. With regard to small changes of magnetising forces, at least, soft iron exhibits what may be called magnetic viscosity—that is to say, the changes of magnetism follow somewhat sluggishly the changes of magnetising force, just as in the stretching and unstretching of a rod of india-rubber by applying and removing weights, the changes of length follow sluggishly the changes of load. If this property exists to any considerable degree in wide ranges of magnetic change, it may have the effect of causing $\int H\,dI$, in a quickly performed cycle, to have a value very different from the value observed in such experiments as have been described.

The whole question of magnetic viscosity is one of great practical interest. Probably it is to direct calorimetric measurements of the heat generated by magnetic reversals that we may most hopefully look for its solution, but direct calorimetric measurements present a good deal of difficulty. They have been made by more than one observer, but the experiments hitherto carried out cannot be said to settle the question raised above. Warburg‡ and Hönig, experimenting with bundles of fine wires (to get rid of Foucault currents), found that the heating effect of reversals, as measured in a calorimeter, was about two-thirds of the value of $\int H\,dI$, as calculated from magnetic observations in slow cycles. Tanakadaté,* using a multiple ring of cotton-covered soft-iron wire, and measuring the heat developed in it by reversals, by noting the rise in temperature of a thermo-electric junction placed under the magnetising coil, found the heating effect of quick cycles to be equivalent to about 80 per cent. of the slow-cycle value of $\int H\,dI$. He observed, further, that the heating effect was practically independent of the frequency of the reversals when that was varied between the limits of 28 and 400 cycles per second. A chief difficulty in observations of this class is to determine what is the actual value which H reaches during rapid alternations of the magnetising current.

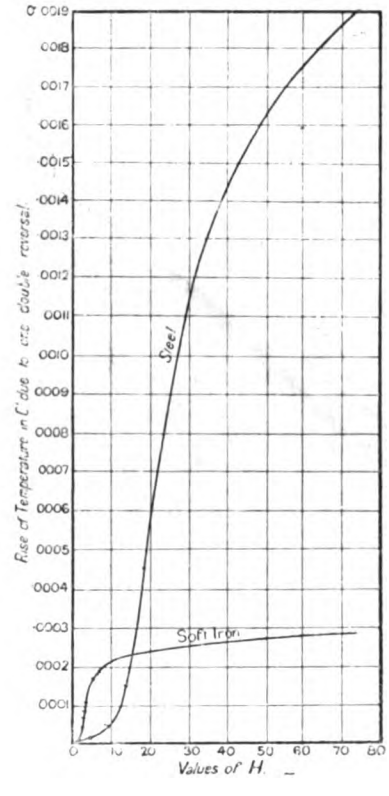

Fig. 53.—Heating effect of reversals of magnetising force in iron and steel.

Though these results are subject to some uncertainty, they concur in making it probable that, for a given value of alternating H, the range of magnetisation is less in quick alternations than in static experiments (where the reversal goes on slowly or by steps with pauses between), and hence that the dissipation of energy in a quick cycle is less on account of this diminished range of magnetic change.

(To be continued.)

Royal Society.—The following were amongst the Papers down for reading yesterday at the Royal Society:—Prof. Rücker, F.R.S.: "On the Relation between the Magnetic Permeability of Rocks and Regional Magnetic Disturbances." H. Wilde, F.R.S.: "On the Causes of the Phenomena of Terrestrial Magnetism, and on some Electro-Mechanism for exhibiting the Secular Changes in its Horizontal and Vertical Components."

THE EDINBURGH EXHIBITION.—I.

The Eastern Telegraph Company's Exhibit.

The exhibit of the Eastern Telegraph Company at Edinburgh is one of the most complete and interesting in the Exhibition, comprising, as it does, examples of the various types of apparatus employed in cable work. A prominent feature of this exhibit are two of Sir William Thomson's syphon recorders. One of these instruments is the second of the kind ever made; and the other is a modern instrument, containing all the latest improvements. The special feature of these, as will be well known to many of our readers, consists of a very fine glass syphon, which brings the ink down from a small ink-well nearly on to the centre of a running slip of paper, so that if it quite touched it would normally trace a straight line. To produce signals the point of the syphon is deflected either to the left or right by the action of the current on a small coil suspended between the poles of a very powerful magnet, the coil being attached to the syphon by means of a very fine fibre. As stated above, the syphon brings the ink very *nearly*, but not quite, on to the paper—it would not do to allow the point of the syphon to quite touch the paper, or the friction would be too great for the received current to overcome. Means have therefore to be provided to spurt the ink from the point of the syphon on to the paper. Formerly this was done by electrifying the ink with a static charge, produced and maintained by the familiar "mouse mill" apparatus and a small induction machine, and so causing the ink to jump off the point of the syphon on to the paper which was connected to earth. This method had its drawbacks, especially in damp weather, when it was found difficult to properly maintain the electrification. However, by keeping in constant agitation the cradle from which the syphon is suspended, the ink can be mechanically shaken off the point of the syphon on to the paper in sufficiently small drops, and the electrification therefore dispensed with. This improvement was devised by Messrs. Ash and Tuck, superintendents in the service of the Eastern Telegraph Company, and is shown working on the new instrument exhibited, which also has powerful permanent magnets in place of the electro-magnets previously employed. The means adopted for producing the vibration consists of a small electric arrangement, similar to a trembling bell movement; but made in a neat form, capable of being attached to the syphon suspension frame of the instrument, and having an adjustable weight, by which the rate of the vibration can be so set as to best coincide with the particular rate at which the globules of ink most readily form at the point of the particular syphon in use.

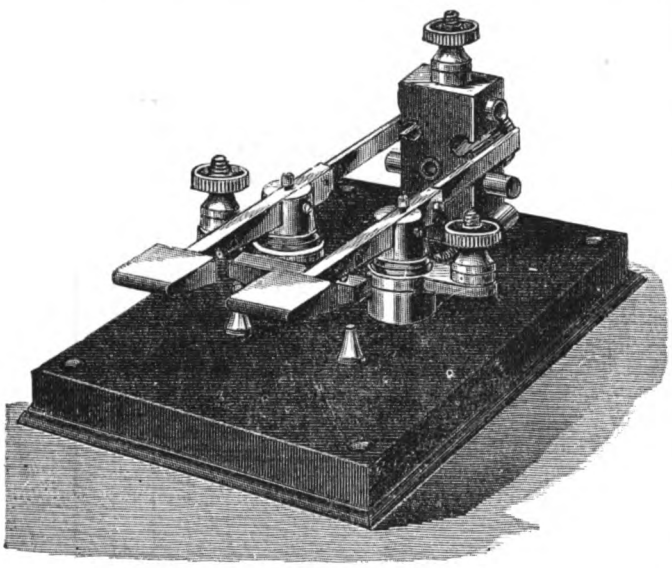

Fig. 1.—Saunders' Reversing Key.

Mr. H. A. C. Saunders, chief electrician to the Company, shows a reversing and a capacity key. These keys (Figs. 1 and 2) have been specially designed for testing purposes on board cable repairing ships and at cable stations. The weak points in the construction of most previous patterns have been avoided in these by the following improvements. Stout brass bars replace the flimsy strips of sheet metal hitherto employed; uncertain contact is prevented by the substitution of broad rubbing surfaces of gold-copper alloy and platinum; cams and similar devices for holding down the levers of the keys (always fruitful sources of error and trouble) are rendered entirely unnecessary by the absence of springs. An insulated rocking beam, a device due to Mr. Saunders, is pivoted beneath the front parts of the levers, so that the depression of the one lever causes the elevation of the other; thus, in the reversing key rendering any short-circuiting impossible, and in the capacity key enabling the discharge of cable and condenser to be rapidly effected when taking Thomson's capacity test in the manner adopted by Dr. Muirhead.

Another exhibit, which is to be seen at work, consists of an automatic Morse apparatus, devised by Messrs. Saunders and Brown, on which the paper strip is driven electrically by the same current that operates the signalling armature. This current is supplemented, if need be, on long lines, by a local battery, but in such a way that the paper starts running immediately the sender at the distant end commences operating, and stops shortly after he ceases, always continuing to run long enough, however, to bridge over any short pauses in his sending. The complication of clockwork with its attendant evil, winding, is therefore dispensed with entirely; and, providing a sufficient supply of paper slip is left in the drawer, the instrument is capable of receiving a message in the absence of a receiving clerk, a few spare movements of the sending key at the transmitting station at the commencement of a message being all that is necessary to start the paper slip at the receiving instrument.

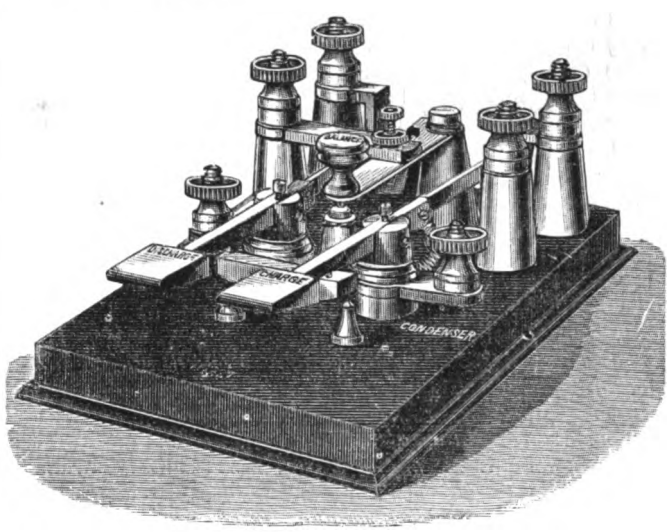

Fig. 2.—Saunders' Capacity Key.

There is also on exhibition a well-finished model of the improved form of bow gear for cable operations, as made for the Company's steamship "John Pender," and designed by Mr. Isaac, the Company's superintendent engineer. This arrangement is to supersede the old system of carrying the bow sheaves on wrought iron girders, which occupy considerable width, and in the latest cable ships has necessitated the spreading out of the bow. This, when the vessel pitches, causes inconvenience, and at times the starting of the butts of the plating. The improved arrangement is made entirely in cast steel, and enables the bow gear to be fitted into a cut-water bow, and at the same time preserves the handsome outlines of the head. The weight of the new gear, with three sheaves, is 4 tons 9 cwt., against 7 tons 5 cwt. for the old gear, with only two sheaves. This saving of top weight is also a point in favour of the ship. The present model and the actual bow gear for the vessel have been made by Messrs. Johnson and Phillips. Another exhibit is a model of Sherlock and Pattison's ship's tell-tale telegraph,

Digitized by Google

designed so as to give a warning signal in the event of a ship's engineer mistaking, or from any cause improperly executing, an order given on the ordinary ship's engine-room telegraph. This consists of an arrangement having a mechanical connection directly with the engines' reversing gear, and working in conjunction with the pointer of the ordinary ship's telegraph in such way that an electric contact is closed whenever the position of the reversing gear does not coincide with that which it should occupy to properly carry out the order last given. When the proper coincidence of the reversing gear with the telegraph hand is established, this contact is broken. It is needless to add that a battery and electric bell, or other means of producing a sound, is joined up in circuit with the above-mentioned contact, and thus serves to give a continuous warning to the engineer; and also, if so desired, to the captain as long as any order from any cause remains unexecuted or improperly carried out.

There are also working two call points and a station indicator, of Saunders and Brown's fire alarm telegraph system, as used by the Metropolitan Fire Brigade in the streets of London. This apparatus embodies a number of practical details found necessary in the actual working of fire alarm telegraphs. Thus it gives an effective call, irrespective of an excited caller's action with the knob, after he has once pulled. It keeps the line under continual test for contacts, &c., but makes a distinction between rings arising from such causes and real calls from the call point. It enables replies to be sent in answer to the calls and conventional signals to be sent by the firemen, both from and to the posts without requiring any batteries in the posts. An additional feature of this system, due to Mr. Lewis, General Manager of the Western Counties and South Wales Telephone Company, consists of a loud ringing alarm bell placed within the post or immediately above the wall box, out of reach of the person giving the alarm. This bell is rung immediately the knob is pulled, and not only acts as a powerful fire alarm notice to the police or passers by in the road or street, but leads to the detection of persons giving false alarms. The knowledge of this acts as a great deterrent upon mischievously inclined persons.

The remaining exhibits comprise a model of the Company's twin screw cable steamship, "Mirror," showing all the cable machinery; a large and accurately drawn map, showing the position of the Company's cables and land line connections throughout the world; and a Saunders' lightning guard (see *The Electrician*, April 27, 1888).

The London and North-Western Railway Company's Exhibit

This Company show a large number of electrical appliances employed in railway working, and the following is a brief description of the more important of these exhibits:—Persons conversant with the regulation of traffic on important lines of railway are well aware of the waste of time that occurs when a man from the station has to accompany a train with a key to unlock a siding; and amongst the apparatus displayed by this Company is an electric locking system, devised by Mr. Fletcher, their telegraph engineer, to do away with this delay, and electrically control sidings, &c., situated at too great a distance to be worked in the ordinary way with rod and lever. In the normal state of the arrangement the signals at the signal-box are unlocked and those at siding are locked, this state of affairs being maintained by the constant flow of current through electro-magnets. If a train has to call at the siding the signalman, by the insertion of a common carriage key into his instrument (provided always that the signals are at "danger") disconnects the circuit, with the result that the signals are locked and the lever at the siding unlocked. When the train is ready to proceed forward the reverse process is effected. Another piece of apparatus is the "Tell-tale" instrument for permissive working. The instrument is somewhat similar to the ordinary 3-wire instrument, with the addition of a commutator fitted with a revolving disc, lettered "Line closed," "Line clear," "Train on line," and Nos. "2" to "6" on the remaining sections of the disc. As additional trains are admitted into the section, a corresponding portion of the disc is brought forward, and as the trains pass out of the section the same disc is moved back, section by section, until the line is clear. A constant reminder is thus afforded to the signalman of the number of trains there are in his section. Some electric fog horns and detonators are also shown. The starting and stopping of the apparatus is caused by the passing trains actuating treadles, not by actual contact, but a depression of the permanent way; the fog horn is worked by a small motor, attached to a bellows arrangement which supplies the required pressure of air to blow the horn. The electric detonator acts by means of an electro-magnet and armature, and is capable of discharging 50 fog cartridges without attention. While a train is in the neighbourhood of the "contacts" the apparatus continues in action, but the signalman has the power to put it out of circuit at any time. One of the most important matters in connection with a railway is the outdoor semaphore signals, on the maintenance of which in a state of efficiency the safe and punctual running of trains in a very great measure depends. Some of these signals have perforce to be placed out of sight of the signalman, and it is necessary that he should have some means of ascertaining the state of the signals. Until recently electric repeaters provided for this purpose have only showed signal *on* by current and *off* by gravity. The form of instrument, due to Mr. Fletcher, now in use on the London and North-Western Company's system, shows:—Signal *on* by current, signal *off* by current, signal *wrong* by gravity, light *in* by current, light *out* by current; and these five indications are given by means of one wire only. The watchman's tell-tale apparatus, adopted by the London and North-Western Company in all their large goods yards, is briefly as follows:—An intermediate indicator is fixed wherever it is necessary for the watchman to visit, and at each of these places the circuit is broken, so that the watchman has to turn a key in each indicator to make the circuit good. At the end of the circuit there is a terminal indicator, and the first result of the turning of the key sends a positive current to a clock, recording the time of the completion of the journey. The key, however, cannot be withdrawn without turning the commutator completely round, resulting in the reversing of the current, which causes the whole of the "bridging" pieces in the intermediate indicators to fly off, leaving the circuit broken down, and compelling the watchman to go round again and perform the same manipulation at each point before he can make another record on the paper at the clock.

Exhibit of Woodhouse and Rawson United.

In addition to a large display of measuring instruments, switches, and cut-outs, this firm shows one of Commander Percy Scott's flash-signalling lanterns, which has been designed with a view to enable flash signals to be sent on the Morse system with greater rapidity than has heretofore been possible, and from a point where the present mechanical arrangement of shutter could not well be employed. The lamp is surrounded by a number of vertical shutters, pivoted above and below, and engaging by means of short arms or toothed wheels a central wheel. The motion of the latter is produced by an electro-magnet action against the force of springs. When the magnet is energised a rapid but short movement of the wheel takes place, opening the shutters for a longer or shorter period as desired, and producing thereby longer or shorter flashes of light. The action of the springs carries the wheel back to its original position as soon as the current is broken in the electro-magnet. The electrical circuits are arranged in a special manner, with the view of avoiding running the lamp at full incandescence during the time the shutters are closed. The magnet coils are therefore put in circuit with the lamp, the resistance of the former acting so as to dull the incandescence, but only to such a point as will allow the thick filament necessary for the 100 candle-power lamp employed to rise to its full incandescence during the period of the shortest flash which may be found possible to use in practical working. In order to further reduce the strain put upon the lamp by the heat developed during continuous running a special switch is employed. The handle of the switch is hinged in such a way that under normal conditions a strong spring is pulling upon the end of it and breaks the main circuit to the lantern. In order to commence signalling it is necessary to pull down

Digitized by Google

the handle against the force of the spring. This completes the circuit to the lantern, and a further depression similarly to a telegraph key operates the shutters. The contacts are so arranged that in the act of opening the shutters the lamp and magnet circuits are momentarily in shunt to one another; and as the E.M.F. absorbed by the magnet coils is only 8 volts, the amount of sparking during signalling is very small. Extra contacts are attached to the switch to enable a Morse instrument to be added whereby the signals may be automatically recorded in the same way as in telegraphy. The lantern has been in work for several months on board H.M.S. Northumberland. It is hoped that by means of this lantern it may be possible to attain to such speed in flash signalling that the two services may be able to interpret each other's signals, which at present is found to be impossible owing to the widely different rates at which the signals are sent by the two.

Another exhibit of this firm is Horn's electric tachometer for indicating directly the speed of a rotating shaft. The action of this instrument, as is well known, is based upon the fact that electric currents are set up in a copper disc when it is rotated in a magnetic field. The instrument comprises a powerful horse-shoe magnet and an armature which consists of a ring of copper mounted on a spindle, which is driven by a band from the shaft, the speed of which is to be measured. Within the copper ring there is a soft iron bar. This bar is constrained by the magnet to take up an axial position between its poles, and to form a direct path for the lines of force between the poles; but immediately the copper ring commences to revolve the currents in the copper tend to rotate the bar on its axis, and thus it moves from its horizontal position until it finds a point at which the influence of the magnet is balanced by that of the Foucault currents. An arm on the spindle carries

Horn's Electric Tachometer.

a curved rack, which gears with a pinion on the index spindle, and thus the movement of the bar is greatly magnified upon the dial. The accuracy of the indications is not dependent (within limits) on the strength of the magnet, since the two forces acting upon the bar vary together. Several specimens of a new insulating material (the main constituent of which is Portland cement), suitable for the bases of switches and other work requiring high insulating properties, coupled with uninflammability, are shown by this firm.

Messrs. Carrick and Ritchie, hydraulic engineers, in addition to a number of their well-known Waverley turbines, show a Girard turbine, specially made for high falls up to 300ft. or 400ft. To illustrate what can be done by applying the ordinary town water supply to produce power, a small jet motor is fixed, and is shown at work driving a dynamo. The water is taken from the main pipe in the Exhibition, where there is a pressure of about 50lb. to the square inch. The water, after being used in the motor, is returned to a large tank, and used for feeding the boilers. This motor uses the water in an economical manner, as it has two jets, both of which can be used when all the power is required, and one only when less than the full power is wanted. By this means the pressure of the water is not lessened by being drawn through a partly-closed orifice, but is allowed to pass into the machine with the full pressure in the pipe due to the head. Riveted steel pipes, which are fast superseding cast-iron ones, for the conveyance of water to turbines and for other purposes, are also shown. The Magnolia Anti-Friction Metal Company of Great Britain exhibit a number of bearings made of this metal, which have come successfully through a variety of severe practical tests. Messrs. Faraday and Sons' exhibit consists of a fine display of the artistic electric light fittings, for which their name is so well known. The most noteworthy are the new shrine lamp in pierced and repoussé metal, resembling the delicate Venetian work of the seventeenth century; bronze and silver from models of the Rénaissance bearing electric torches or cressets, and standards or tripods; and Sir David Salomons' adjustable reflecting pendant and "universal" wall plug Messrs. Cox-Walkers make a good show of their specialties. One of their well-known watchmen's electric tell-tales for 24 stations has been connected to stations all over the buildings, and is now in regular use by the watchmen. This firm have also provided and erected for the use of the Exhibition authorities 24 fire-alarm call-boxes, and seven or eight indicators fixed in various suitable positions, with one main one in the central fire station. Anyone pulling a knob at any of the alarm cases drops an indicator at all the places, showing where the alarm is given from, and rings a bell at the alarm case and large bells in numerous parts of the buildings at the same moment. Magneto keys or tappers and sounders for telegraphing the Morse alphabet without batteries, which should be very valuable for military and similar purposes, are also shown by this firm, who have also fitted up the electric signalling arrangements for the ship railway.

(To be continued.)

ELECTRICITY IN THE NAVY.*

BY GILBERT WILKES, U. S. NAVY.

I have taken as my title "Electricity in the Navy," and shall give in my Paper the general conclusions derived from five years' more or less intimate connection with the application of electricity in our naval service. The electrical engineer has little to do with the placing of the dynamo room, which is of necessity governed by the arrangement of the ship as a fighting machine. I shall, therefore, merely consider the power and apparatus of the plant, commencing with the engines. Both in this country and abroad compound condensing engines have been used, some having separate condensers, some exhausting into the main condensers of the ship; but the preference seems to be in favour of simple double acting, high-speed engines, the reason being that the power used for electrical purposes is so small in proportion to that of the main engines of the ship (only about an average of 1 per cent.) that the saving does not pay for the additional complication and cost. However, with a given plant, the engine should be constructed to allow little variation of speed under large changes of steam pressure, in order to take advantage of the main condenser when possible. In our service both horizontal and vertical engines are now in use, the preference in some cases being the result of the shape of the available space. No data have yet been obtained as to the most economical type, but both are doing good service, the mishaps having been due to accident. Of late years all of the engines put in for electric lighting have been high speed, the largest of about twenty-five horse-power and running at 400 revolutions.

The important points in the consideration of a marine dynamo are:

First.—It should be direct driven. The reasons are obvious, as not only is the space taken up by the belting valuable, but in a sea way the danger of running belts must be considered, especially when it is taken into account that naval vessels are fighting machines, and the possibility of accidents must be reduced to a minimum.

Second.—It should be compact. This is a natural extension of the above. Even now it is difficult to find room for all the machinery, stores and ammunition, besides providing room for berthing the crew on a modern man-of-war.

Third.—It should be free from liability to injury by salt water, and not too subject to mechanical damages.

In this respect there remains room for considerable improvement, the latest dynamos now better filling this requirement than did the old "L" machine on the Trenton in 1883, the first dynamo afloat in our navy, and which ended its useful career in the great storm at Samoa last year, when it ran until the water had put out the fires under the boilers. On board ship salt water and damp air get

* A Paper read before the American Institute of Electrical Engineers, New York, May 20 1890.

Digitized by Google

everywhere, and within the last year a number of cases of slight burn-out have occurred in armatures, which, when installed, measured high in the hundreds of thousands of ohms insulation. The dynamo should not be easily harmed. The dynamo room is now always low down in the ship, under the protective deck (if there is one), and when the light is not in use the room is very dark, rendering careful inspection difficult.

Fourth.—The dynamo should have small effect upon the compasses. This point has received little attention, though it is a matter of great importance, as the effect on many vessels is so large that, in order to work up the day's run, it is necessary to know the hours during which the dynamos have been in operation. Complete deviation tables are, therefore, necessary for the two cases. In different types of dynamos the effect with a twenty horse-power machine, at a distance of twelve feet, will vary from less than one-twentieth of the horizontal component of the earth's magnetism to several times the strength of the horizontal component. The latter is, unfortunately, rather the rule than the exception, and, in consequence, the position of the dynamo room has to be well borne in mind in locating the standard compass.

Fifth.—It should be easy in running and require but little attention. The machine should be non-sparking, under constant load, and also be able to stand sudden large changes of load with little sparking. This is necessitated by the fact that the dynamos now supplied for incandescent lighting are also used for search light work, and the conditions are aggravated by most of the search lights having hand regulation only. Thus, with a 200 ampere machine, not only are from 50 to 100 amperes thrown suddenly on and off, but, at the moment that the operator at the projector brings the carbons together, the dynamo is suddenly called upon to deliver over three-fourths of its total capacity.

Sixth.—It should be efficient and run cool, the former in order to avoid the waste of energy and a corresponding amount of the coal supply, and also in order to avoid overheating. The dynamo rooms on ship board are, at best, warm, notwithstanding the motor fans, which are now usually supplied, and thus the safe limit of extra heating is reduced. At the same time, consideration for the attendants requires that the cramped space be kept as cool as possible.

Seventh.—The dynamo should maintain a constant potential at all loads. This is, of course, accomplished by compounding, and, as there is only about 3 per cent. drop, it is usual to compound exactly, or to only overcompound enough to allow for the decrease in the engine's speed with load.

Eighth.—The dynamo should be light. The reasons are obvious, but it is considered last, because usually a careful study of the materials, and arrangement of the plant, can accomplish more towards reducing the total weight than the strict adherence to a specification of watts per pound of dynamo. Thus, consider the difference between the weight of a 40 horse-power ship plant on a five watts per pound specification and upon a four watts specification. Two 200 ampere, 80 volt dynamos, with their share of the bed-plates, will only weigh about 7,500 pounds. Twenty per cent. of this will be 1,500 pounds, an amount a large portion of which can really be saved in some cases by more careful attention to the amount of wire and moulding employed.

Naturally no one dynamo can best fill all of these conditions, and while the order in which they are above arranged will usually approximate to their relative importance, special cases arise which demand a re-arrangement. Thus, on torpedo boats, the most important quality is small size. With this in view, numerous devices have been placed upon the market and faithfully tried, but none have to my knowledge proved satisfactory. The requirements of high efficiency, low speed and low heating, all give way in this class of dynamo to the necessity of compactness and light weight. Good results were hoped for from the Parsons turbo-electric generator, but experience at Newport demonstrated that the turbine was so inefficient in its consumption of steam as to place its use out of the question. There is as yet no apparatus to satisfactorily fill this want. Up to the present all of our ship plants contain two or more similar sets, each composed of an engine and one direct driven dynamo. The larger of these are of 200 amperes capacity; a very convenient unit, but one which can be doubled in capacity with advantage in ships which are not light below decks and which are likely to soon have extensive motor application; for example, vessels of the monitor type. The voltage in use in the navy is 80 volts, this having been fixed upon as a mean between the most efficient pressure for the incandescent system and the voltage necessary for the search lights, to which current is supplied by the regular service machines. The incandescent lamps have given excellent results as to life from the very start, owing in great measure to the fact that low efficiency lamps are always used, nothing more economical than four watts per candle-power being usually required. Search lights of 50 volts and from 50 amperes up are used, two or more being supplied, according to the size of the ship. Some of these are imported, others are made in this country. The two-wire system has always been used in the naval service, the ship never being allowed to form the return circuit. On account of the present beginning of motor work on board ship and the future developments confidently looked for, the direct current has always been used. Motors have thus far been used only in driving small fans up to one-half horse power, for hoists, and in one case a motor has been used for training one of the large guns—on the "Chicago." There are numerous small engines about a man-of-war, varying from 1 to 50 horse-power. Some of the smaller ones might even now be replaced with advantage by electric motors; but it must be proved in each case; that the motor not only does the duty as well as the engine it replaces, but also that it and any increase necessary in the generating plant take up less room and weigh less than the engine and its piping. This, of course, will always be the case where very small engines are replaced, and as the tendency is to increase the capacity of the dynamo plant, it may not be long before motors may look for a larger field on board ship.

All circuits are water tight from dynamo to point of distribution, the cut-outs having stuffing boxes through which the lead-covered wires enter. Even the switches and attachment plugs for portables are required, in certain places, to be water tight.

One electrical application that presents many advantages on board a man-of-war, especially when on a foreign station, is electrical welding. However, when it is introduced on ship board, the pressure of the generator should be reduced to 80 volts, in order that in case of emergency it might be used for lighting purposes, while the welders should have several sets of adjustable clamps. Welding machines have not yet been actually used on ship board, but it is to be hoped that their introduction is a development of the near future. They cannot supplant any of the existing dynamos, owing to the necessity of motors, but must come in to occupy a place of their own, to almost entirely supplant the ship's forge and add to the general useful equipment.

Thus the man-of-war is the proper field for nearly every form of application of electricity, and when the storage battery becomes more suited to the service there required, there is no doubt that it too will come in for its proper share of usefulness.

As to the naval work on shore in the electrical field, little need be said, as the practice at naval stations must be similar to that in ordinary commercial work. However, a navy yard is an ideal place for the erection of a central station for light and power. The streets must be lighted; closely grouped about the station are offices and large shops needing light in the dark afternoons, and power for motor work; then in an outer approximate semi-circle lie the officers' quarters; finally, there are anchor chains to be welded, boiler tubes to be repaired, and numerous other similar operations which can be better accomplished by the welder than by any other known means. This in an ideal plant will call for arc lights, incandescent lights, constant potential motors, a welding generator and welders. The complete combination will probably not be realised at any one place within several years, but a good beginning has been made in the arc light plant recently installed for outside and shop lighting at the Washington Navy Yard, and the progressive plan adopted by the Department leads us to hope that the shore stations will rapidly receive the benefits already enjoyed on ship board. Owing to the usually close grouping of the buildings and to the demand for motors, it is probable that only in exceptional cases will the alternating current be used extensively. Good use is already being made of small motors for drilling purposes at the New York Navy Yard, where several are in constant operation, having driven out the portable steam engine, counter-shafting and belting.

The applications of electricity in the navy have always been on the increase, and any one who has served one cruise with oil lamps and one with electric lights and motors will understand the favour in which the increasing use of electricity is held by the naval man.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, June 20th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: "The Stretching of Liquids." By Prof. A. W. WORTHINGTON. "The Measurement of Electro-Magnetic Radiation." By C. V. BOYS, A. E. BRISCOE and W. WATSON. "Notes on Secondary Batteries." By Dr. GLADSTONE and W. HIBBERT.

FRIDAY, June 27th.

SOCIETY OF ARTS.

9 p.m. Conversazione at Natural History Museum, South Kensington.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Digitized by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and be crossed* "*Coutts and Co.*"

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

THE ABUSE OF PATENTS.

Rumour of a very authoritative sort is rife that before the year is out there will be a renewal of those judicial combats which in the past have proved so disastrous to the progress of the electrical industries. We say "disastrous" advisedly, because few circumstances could be more prejudicial to the welfare of the industry as a whole than that entire branches should fall into the hands of monopolists who use their position to crush out all progress in hands other than their own. The state of telephony in this country is a standing witness to the paralysis that accompanies the establishment of an unwieldy monopoly. A legal terrorism has been established over small traders, out of whom no judicial decisions can ever efface the sense that they have a moral right to sell and use an invention which, like the microphone of Prof. HUGHES, was given to the world free of all patent-rights or restrictions. Following hard on the heels of the telephone litigation came that on the incandescent lamp—resulting in an equally disastrous issue. A single word in a single claim—a word which not even the patentee attempts to define—a word which has been legally twisted to cover things undreamt of at the date when it was written, bars the way to the progress of an entire industry, and establishes a monopoly of manufacture for the assignees of an inventor whose exceeding cleverness in inventing new names for old things has been thus twice legally established. To use a patent in this manner in monopolising a branch of industry for the benefit of a single firm or company which contributed nothing whatever to the preliminary stages of its progress is a flagrant misuse of the forms of law,

Digitized by Google

and one which public opinion will not in future permit to go unchallenged. The so-called "fundamental" patent, or "blanket" patent, as our American cousins call it, covering the ground of a whole industry, is a moral impossibility. As a fact, inventions do not start full-fledged from the brain of a single man of genius; and the fundamental character of a claim in a patent specification can usually be only established by reading into its words a meaning which originally it was never intended that those words should possess. We cannot forget how ten years ago an attempt was made—happily an abortive one—to secure in this country a monopoly of dynamo machines for the company owning the patent of M. GRAMME, on the ground that, though GRAMME's claim was only for a particular way of winding wire on a ring armature so as to cover its surface all over, there were no commercial dynamos before GRAMME's. Neither can we forget how the Cheesborough patent has been legally converted into a claim for the flashing process; nor how the monopoly of gas engines was sustained, to the detriment of the industry, in claiming for a single firm the sole right to use the cycle of operations invented by DE ROCHAS fourteen years before OTTO's rediscovery of it.

Fortunately for the electrical industry, two recent cases have done much to check the scramble for judicial monopolies. The claim for the monopoly of the compound-winding of dynamos in the name of BRUSH, which was for long unchallenged, received last year a rude shock in the Scottish Law Courts. As the appeal in this case is *sub judice*, we must not comment on the matter further than to remark that in this instance the attitude of the holders of the English patents was far more liberal than in some of the cases previously referred to; inasmuch as the BRUSH COMPANY was contented with a moderate royalty, and did not attempt to secure to themselves a monopoly of manufacture. The other case is furnished by the action about the Gaulard-Gibbs patent for secondary generators: which patent was put forward as ground for a fundamental claim to the entire system of electric distribution by induction coils, but collapsed when the action was tried.

Some of the rumours now rife relate to an obscure patent which—so report says—is now being trimmed into shape so as to afford a legal claim to the entire use of closed-circuit transformers for central-station lighting. Other rumours affirm that the Edison "feeder" patent has been exhumed—one of the forty or fifty patents relating to electric lighting from the same hand—for a similar exclusive purpose. It is alleged that a legal disclaimer is now being prepared and presented to the Patent Office, which, if granted, will, in the opinion of experts, give to the owners of the patent the exclusive right to the modern system of using on a lighting system feeders which are not the ordinary mains. Another rumour, which, if less precise is more persistent, alleges that the EDISON-SWAN COMPANY is about to claim the sole right to use the cut-out devices which are a necessary part (owing to fire insurance rules) of every installation. Lastly, we have the remarkable *pronunciamiento*, published in the name of the LANE-FOX ELECTRIC COMPANY, breathing out, metaphorically, fire and sword against all who use accumulators with their electric lights, unless they are willing to tax themselves to the tune of one-eighth of the highest price at which electric energy may be charged in a public supply.

Against all such schemes for hampering the electrical industry for the benefit of monopolists a firm stand has been taken by the voluntary association in mutual self-defence of representatives of all the chief companies now holding Provisional Orders for the public supply of electric light and power within the metropolitan area. It could not be expected that important bodies like these could leave the fight against monopolies to the isolated action of small firms or single-handed defendants, as happened so disastrously in the litigation about the telephone and the incandescent lamp. Those who in their haste to get rich forget the old adage live and let live, will now find a wholesome corrective to their proceedings. No reign of terror can be established over the manufacture of induction-coils, the use of accumulators, or the employment of safety-fuses. If the monopolists endeavour to grab these things and saddle the industry with new disabilities, they will find the whole industry rising up to oppose them in the law courts. Blanket-patents are undoubtedly admirable for the owners—and for the lawyers: but they are essentially unjust, and the electrical industry will not readily consent to allow any more of them to bar the way to progress.

REVIEWS.

Electrical Engineering for Electric Light Artisans and Students.—By W. SLINGO and A. BROOKER. (London: Longmans Green, and Co.)

Of text books dealing in a more or less satisfactory manner with the elements of electricity and magnetism we have enough and to spare; and the supply of treatises on particular branches of electrical engineering, such as land line and submarine telegraphy, telephony, dynamo design, transmission of power, and alternate-current machinery, is also fully equal to the demand. But the student who, having mastered the initial difficulties of the science, is desirous of obtaining an accurate general notion of its practical applications, has hitherto been without a suitable work. The volume under consideration may, however, be fairly held to meet this want. The style is simple, and the explanations of electric and magnetic phenomena are clear and accurate. The authors have, moreover, taken great pains to keep their work well up to date, and to present things in something like their true proportions. Their readers are not treated, for instance, to pages of description of various palæozoic magneto-machines, nor are they in danger of rising from the perusal of the chapters on dynamos with the firm conviction that Lontin's dynamo and the Mordey alternator compete on about equal terms for the public favour. The book is one which is likely to prove of great value to a large class of readers.

The work contains seventeen chapters, the first two of which are devoted to a brief consideration of elementary principles. Chapter III. deals with primary batteries, and chapters IV.—VI. with electrical measurements and measuring instruments; the latest and most generally used apparatus being alone described. Chapter VII. treats of electro-magnets and electro-magnetic induction. We may remark in passing that the authors appear to hold by the old idea that the introduction of an iron core into a coil of wire carrying a current has merely a *concentrative* and not a *creative* effect as regards the lines of force. The next four chapters are occupied with the subject dynamos, which the authors succeed in rendering very clear and interesting to the student, who is not troubled with the details of any but the best types of modern dynamo machines. Motors, transformers, secondary batteries, and arc lamps, are next touched on. Chapter XVI., which is devoted to incandescent lamps and photometry, is an especially good one. The manufacture of incandescent lamps is described as fully as can be expected, and the authors are at some pains to demonstrate "the utter unreliability of the standard candle." The last chapter deals with conductors, fittings, meters, &c.

The authors, it will thus be seen, cover the ground of electric light and power engineering; and we do not think that with the generic title of "Electrical Engineering" which they have chosen for their work, it would be unduly enlarging its scope if concise chapters on land line and submarine telegraphy and telephony were to be added in the next edition.

THE INTERNATIONAL TELEGRAPH CONFERENCE.

On Tuesday last the representatives of the Submarine Cable Companies, now present in Paris, entertained M. Jules Roche, the Minister of Commerce, Industry, and the Colonies, and a number of delegates at the Hôtel Continental. The luncheon was given by the following Companies:—The African Direct, the Anglo-American, the Brazilian Submarine, the Cuba Submarine, the Direct Spanish, the Direct United States, the Eastern, the Eastern Extension, the Eastern and South African, the Great Northern, the Black Sea, the Indo-European, the Spanish National, the West African, the West India and Panama, the Western and Brazilian, and the Western Union.

The chair was taken by Sir John Pender, K.C.M.G., and M. Roche occupied a seat on his right. Amongst those present were:—The Marquis and Marchioness of Tweeddale, Mdme. Roche, Sir James Anderson, Sir E. Vincent, Baron d'Itapiba, Commander Nielsen, M. Hake, Commander Ponzio Vaglia, Chevalier d'Obentraut, the President of the Havre Chamber of Commerce, M. Baron, M. Marguerittes, Mr. Palmer, M. Mansi, Sir A. J. Leppoc Cappel, Sir E. Blount, Mr. Lamb, Sir F. Dillon Bell, M. de Selves, Comte de Lesseps, General Besack, Baron Pfeffel, General Agha, Colonel Höncke, Dr. Benesch, Dr. Rothen, Dr. Gollner, Artin Pacha, Tigrane Pacha, Admiral Vallon, Colonel Mallock, Captain Suenson, Don Vazquez, the Rev. H. Hart, Mr. R. K. Gray, Mr. Thomas Fuller, Mr. C. Burt, Mr. W. Andrews, Mr. G. von Chauvin, Mr. Mourlon, Mr. G. Draper, Mr. F. E. Hesse, Mr. F. C. C. Nielsen, Mr. Moll, Mr. C. W. Earle, Le Vicomte Reverend, Mr. Fischer, M. Despecher, M. Blowitz, Mr. Payton, M. Le Sage, Mr. Beaumont, M.P., Mr. Gerhardi, Mr. Ansell, Mr. Wells, M. Serpos, Messrs. Hofstede, Neuman, Tomara, Vigil, Kurino, Seghin, Bordelongeu, Becu, O'Brien, Garambois, Braive, Neubauer, Radcliffe, Mattheeff, André, Hlaweek, Raymond, Marsilly, Broquisse, C. Clarke, Fribourg, Gatliff, Gramaccini, Frouin, Hibberdine, Condie-Stephens, Coromina, Crawford, Uddenberg, Favette, Moret, Bocher, Benton, Menier, Ansault, de Laboulaye, Goldschmidt, Olivarius, Melcom, de Baudel, Willan, Depelley, Scheffler, Tessier, Dimitresco, Ivasakai, Dürr, Nerot, Desmazières, Barker, Neilson, Greer, Tourtay, Dumas, Caso, Frayssinier, Soutzo, Ivanoff, Cordero, Peyerle, Sieblist, Seligman-Lui, Mongenast, Gvozditch, Van Eck, Forestier, Rebuffel, Bugge, Mooney, Smith, Lanng, Tsubono, Berthot, Aylmer, Perk, Bluet, Köller, Antonopölo, Gody, Phakdi, Eschbaecher.

During luncheon Sir JOHN PENDER proposed "The Health of the President of the French Republic, the Queen of England, and the Reigning Sovereigns and Presidents of the World." He then rose and proposed "The Health of his Excellency the French Minister of Commerce, Industry, and the Colonies." In doing so he said: The gentleman whose health I am about to propose presides over the commercial destinies of this great country, and his position is of the highest responsibility, and, let me add, is no sinecure. We are well aware of his ability to direct great affairs, because we have had the opportunity of judging how well he has conducted the Telegraph Conference which is now being held in this grand city. The nations in modern times are all, as we see, most anxious to promote and advance their commerce, knowing that successful commerce makes a prosperous and happy people. France is fortunate in having a Minister who is animated by the highest sense of responsibility attached to the important duties he so ably fulfils. I hope it will not be unbecoming on my part to say a few words in regard to the telegraph companies, representing as I do a large body of submarine and other telegraph companies who are your hosts to-day, and who are at the present moment playing an important part in bringing the nations of the world into closer and more harmonious communication. We may claim to have promoted progress, political, commercial and social. When the history of the last half of this century is written it will be found that telegraphy will occupy an important page. When we take thought of the vast millions of money which are turned over by the nations of Europe in their relations beyond the sea, and when we bear in mind that these operations are initiated, followed up, and completed by the telegraph, we can form some idea of the benefits which our telegraph system has conferred upon the civilised world. Further, when we see the nations vieing with each other in the desire to promote the prosperity of and extend their colonies, and to take their part in the development of Africa, that dark continent which is so much before the public at the present moment, and in the extension of civilisation, we recognise the beneficent fact that telegraphy not only assists in the improvement of the nations themselves, but in the development of trade and industries for the benefit of the teeming millions of the world and in supplying the requirements of humanity. Telegraphy has been the pioneer of this good work. We have just surrounded Africa with our telegraphs, and it is now in almost instantaneous communication with the civilised portions of the world. The systems which I have the honour to represent possess a great international net-work of industrial communication. The mission of telegraphy is to encompass and draw closer the unity and friendship of the nations—in fact, to bring peace and goodwill to the peoples. A few figures, by way of justifying this statement will demonstrate the importance of telegraphy. There are 2,000,000 miles of land lines, valued at 1,550,000,000fr. (£62,000,000). The cables belonging to the Governments at present amount to 13,178 miles, valued at 100,000,000 fr. (£4,000,000). The cable companies have 107,000 miles of cable, costing 900,000,000fr. (£36,000,000), or a total capital of 1,000,000,000fr. (£40,000,000). The total expenditure on land lines and cables has been 2,500,000,000fr. (£100,000,000). The cable ships employed in keeping these cables in repair number thirty-six, with a tonnage of 53,780 tons. I may say that all this has been done within the last fifty years, and the greater portion of the submarine system has been accomplished within the last quarter of a century: it has scarcely yet attained its majority. Permit me to add, for your information, that the time occupied by messages between London and Egypt is twenty minutes, Bombay considerably less than an hour, China two hours, Australia less than three hours—that is for business messages. Between London and New York the time is 2min. 40sec. It is an axiom that countries which acquire colonies and desire to keep their place in the vanguard of progress must have their colonies connected with the mother country by submarine cables. I hope your Excellency will gather from these remarks the great influence which these companies have had and are having in promoting the commerce of the world. I believe our beneficent work is appreciated by each of the nations, and by none more than the great people whose commercial interests are presided over by your Excellency. I give you the toast of "Jules Roche, the Minister of Commerce, Industry, and the Colonies," whose health I now ask you to drink.

M. JULES ROCHE, who was repeatedly cheered, replied as follows:—I thank Sir John Pender for the extremely kind and cordial words which he has spoken in regard to myself. I have not so far forgotten the English that I learned at school as to fail to grasp the leading points of his eloquent speech. He was anxious, so far as I was concerned, to throw into his speech as many fragrant flowers as those which grace this table. But I forgive him the more readily from the fact that I transfer to the Government whom I have the honour to represent all the flattering things that he has said in regard to myself. Gentlemen, I thank you also; I thank all the telegraphic companies, foreign and French, who have invited us to this gathering under the presidency of Sir John Pender; and especially because they afford me the opportunity of greeting—for the last time, to my great regret—the members of the International Telegraph Conference who have just been, for our pleasure and our honour, our guests for a month. In the picture that Sir John Pender has traced in so masterly and picturesque a manner of the great things accomplished by private companies, in showing the endless networks that they have thrown across continents and oceans for the transmission of human thought, in his picture of the prodigious rapidity with which the orders of the human will are carried from one end of the world to the other—when, for instance, he spoke to us of business despatches exchanged in 2min. 40sec. between London and New York—he was implicitly passing the most complete eulogium on private initiative and the great things that it is able to accomplish. And when I heard him juggling, as it were, with the hundreds of millions of francs that have been thrown into those vast undertakings, it seemed to me, from my old acquaintance with figures, that I was again taking part in a general Budget debate. But, gentlemen, the telegraph companies are much more fortunate than States, inasmuch as the money they spend is laid out on undertakings that are, all of them, productive, all tending to the progress of civilisation, and to fraternity among peoples; and, unfortunately, we cannot say as much for the money expended under all the Estimates of great States. But the great strides of science induce us to hope that the day will come—would that it would come with telegraphic speed!—when the Budgets of great nations will resemble those of great private companies. I therefore thank all the companies who have invited us to this banquet, and Sir John Pender, who presides over them, for the high example of social instruction thus given us; and I very cordially drink to their prosperity and their health, because their prosperity and their health imply those of commerce and industry, which, as you have been reminded, have been confided to my efforts and to my zeal.

Captain SUENSON, representing the Great Northern Telegraph Company, in proposing the toast of M. de Selves, paid a graceful compliment to France for the charming hospitality bestowed upon her guests. He also thought the practical side of the Conference's labours equally worthy of special commendation. In the name of all the companies present he thanked the Government most cordially for the kindly reception extended to them, and congratulated it upon the appointment of a gentleman so deserving of its confidence in every respect as M. de Selves.

M. DE SELVES, in responding, said he was sure the delegates of the different Governments present at the Conference just brought to a close regarded the representatives of the cable Companies as collaborators who were as useful as they were agreeable. M. de Selves expressed a hope that his Administration would consistently follow the path of liberal-minded progress of which the labours of the Conference had been a happy reflex. One of the greatest honours of his career would be that of having presided over their deliberations, and he heartily drank to the health of all the representatives of the States and the delegates of the companies invited to the Conference.

Sir JOHN PENDER then said: I have one duty, ladies and gentlemen, to perform, and that is to thank his Excellency and Mme. Roche for their presence here to-day, and to express, on behalf of the companies, their hearty appreciation of the way in which you have responded to their invitation, and to offer to the delegates from the different States of Europe our sincere acknowledgments for the kind consideration shown to us throughout the Conference.

LIFE AND EFFICIENCY OF ARC-LIGHT CARBONS.*

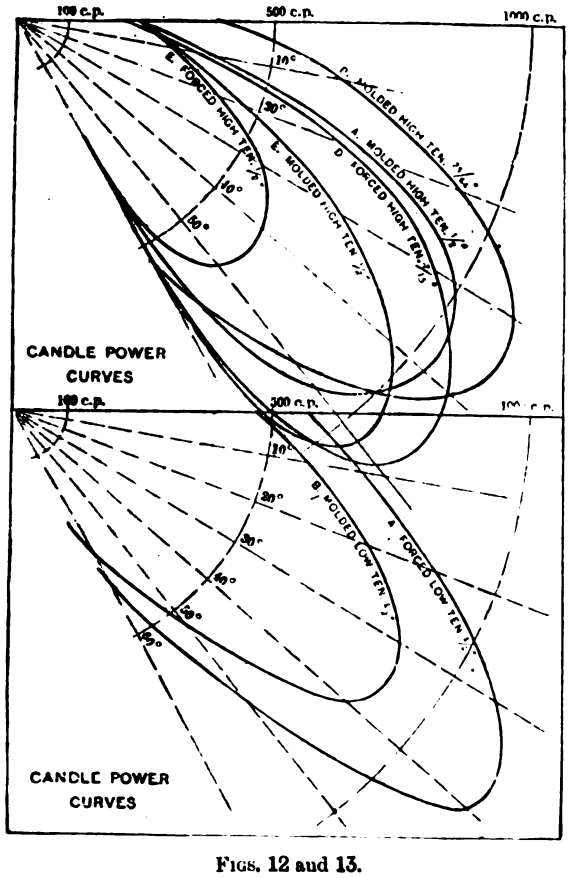
BY LOUIS B. MARKS, M.E.

(Concluded from page 153.)

Candle Power Measurements.

The candle-power measurements consisted chiefly in the determination of the hemispherical candle-power of the different pencils, and from this quantity the watts per spherical candle-power produced. The runs were made under the same conditions as in the efficiency tests. For high-tension carbons, current = 9 amperes and potential difference = 45 volts. For low-tension pencils, current = 21·5 amperes and potential difference = 30 volts. To ascertain the candle-powers, the method of the Franklin Institute Committee was used.† The photometric apparatus was somewhat different in detail from that ordinarily used in measuring the candle-power of incandescent lamps, and deserves a brief description.

The arc-lamp was suspended from an arm which could be rotated about an axis parallel to the photometer-bar and vertically above it. By manipulating a rope connected with the arm, the latter could be raised until it was at right angles with the photometer-bar or lowered until it was horizontal. The arm being horizontal, the lamp was hung from its extremity so that the arc was on a level



FIGS. 12 and 13.

with the centre of the photometer-disc. It will be seen that when the arm was pulled up, the arc described a vertical circle, the axis of which was a line parallel to the photometer-bar and passing through the centre of the disc. The centre of the vertical circle was at the point (800) of a scale graduated into (1,000) divisions, and the radius equal to the length of 200 scale divisions. At the zero of the scale was placed a Weston incandescent lamp and a circular mirror of silvered glass, the axis of which was horizontal, and inclined 45 degrees to the reflecting surface; it was mounted on the bar so that its centre coincided exactly with the 800th division of the scale. Thus the distance between the arc-lamp and the mirror was rendered constant for all elevations of the former, and when the mirror reflected the light of the lamp upon the disc the angles of incidence and reflection were always equal to 45 degrees. The virtual image of the arc under these circumstances was at the 1,000th division of the scale. The Weston lamp was used as a secondary standard and maintained by a storage battery throughout the run at 115 volts; its candle-power was ascertained before and after the tests by comparing it with a standard Methven "Board of Trade" 2 candle-power slit. Photometer readings were made as in the case of the efficiency tests, at 0 degrees, and at 10, 20, 30, 40, 50, and 60 degrees, below the horizontal, the mean of twenty observations being taken for each elevation. These measurements were multiplied by the candle-power of the secondary standard, and corrected for absorption of light by the mirror.

Tables XVII.-XXIII. give the corrected data, which form the basis of the candle-power curves (Figs. 12 and 13). Distance measured along the radii from the origin to each curve give the candle-power for the various angles. The mean spherical candle-power for any case is measured by the radius of a semi-circle whose arc is equal to the area of the candle-power curve. Although great care was taken in ascertaining the candle-powers, the difference in colour between the light emitted by the arc and that given by the standard was so marked that the setting of the photometer-carriage was to a large extent a matter of personal judgment; hence the measurements given cannot be considered as absolute, but rather as relative values.

The conclusions drawn from the efficiency curves hold general, as will be seen by an examination of Table XXIV, for the candle-power curves. From the latter it appears that the efficiency of low-tension carbons, and especially of *moulded* low-tension pencils, is comparatively small. While the efficiencies of moulded high-tension carbons are as high as ·953 and ·888 watt per spherical candle, or 783 and 840 candles per electrical horse-power expended in the lamp, the efficiencies of low-tension pencils of nearly the same diameter as the high are as small as 1·255 and 1·612 watts per candle, or 594 and 502 candles per electrical horse-power. This fact is not brought out in Table XVI., for reference to the latter shows the low-tension pencils to have a rather high efficiency, and in some cases considerably higher than the high-tension carbons. However, when the energy expended in the lamp in the two cases respectively is taken into account, the explanation of the high values for carbons A and B (Table XVI., low tension) is apparent.

Carbon B (moulded high tension, Table XXIV.), it will be noted, has the highest efficiency of the group. This is due largely to the fact that its diameter is smaller than that of any of the others, for "the candle-power varies inversely as the diameter."* Similarly the relatively high candle-power of carbon D is accounted for by the small diameter of the pencil. In Table XXIV. and the candle-power curves we again note the comparatively small efficiency of *forced* high-tension carbons. The efficiency of carbon A (moulded high tension, Table XVI.), as measured by $\frac{\text{luminous radiation}}{\text{total radiation}}$ is larger than that of carbon D; yet the mean spherical candle-power of the latter is greater than that of the former (Table XXIV.). The explanation of this phenomenon, assuming the measurements to be correct, probably lies in the difference in the *quality* of the light emitted.†

In some instances it is desirable to ascertain the mean spherical candle-power of a lamp approximately, without taking the time to integrate the curve. The formula given by M. Gérard, namely, "spherical candle-power = ⅓ horizontal candle-power + ⅔ maximum candle-power" * is of sufficient exactitude for practical purposes.

Table XXIV.—*Candle-Power Measurements.*

Carbon.	Diam. Mean inches.	Resistance. Ohms.	C. Amperes.	P. D. Volts.	Horizontal candle-power.	Maximum candle-power.	Hemi-spherical c.-power.	Watts per spherical c-power.	Spher. c.p. per electrical horse-power.

Data collected from varions sources, including the tests of the Franklin Institute Committee in 1884, show that in some cases the error is less than one per cent. The mean error is, however, larger than that obtained by Gérard himself, and reaches about 9¾ per cent. Hence, as was stated before, the law is valueless except in cases of rough approximation. Reference has been made to the fact that while the curve for luminous radiation is similar to that of candle-power, the curve for total radiation differs widely from the latter. As the efficiency depends upon the ratio $\frac{\text{luminous radiation}}{\text{total radiation}}$ it is plain that Gérard's law will not hold for calculating the mean spherical efficiency from the horizontal and the maximum. But again, for approximations a similar law holds, *i.e.*,

Spherical efficiency = ¼ *horizontal* + ¾ *maximum.*

Although the topic of efficiencies has been discussed in another part of the article, it may not be out of place to add a few words here, bearing upon the law in question. Measurements of horizontal maximum and mean spherical efficiency, made by Mr. H. Nakano and by the writer, are given in Table XXV., and the last law mentioned applied in the calculation of the spherical efficiency. In some cases the error is exceedingly small, while in others it is comparatively large; the mean error of 14 tests is not quite eight per cent.

Observations of the Arc and the Carbon-points.

With a given potential difference between the terminals of the lamp, the length of the arc depends upon the current flowing, and increased as the current becomes greater. If the current be kept constant, the length of the arc increases with the potential difference. Data given in Tables 26 and 27 show the length of the arc for both cases.

In order to measure the length of the arc, a lens was so mounted as to throw the magnified image of the former upon a surface carrying a vertical scale. Then after measuring the distance between the magnified points and applying the proper reduction factor, an additive correction was made for the depth of the crater, thus giving the length of arc from the tip of the minus-pencil to the point directly above in the centre of the crater of the plus.

From the figures (Tables XXVI. and XXVII.), it seems that no direct relation exists between the length of the arc and the current and potential difference. In the case of the carbons tested, the length of the arc with constant potential increased very rapidly as the current was changed from 6 to 9 amperes, and then gained slowly from 9 to 13 amperes. The nature of the change was somewhat different in the constant current runs, the length of the arc increasing more nearly as the square of the voltage.

After each of the runs noted in Tables XXVI. and XXVII., the carbon-points were examined, and it was found that the latter assumed particular shapes depending upon the current and potential difference used. Another series of tests were made with carbons C. and E. (moulded high tension), in which the current ranged from 5 to 15 amperes, the potential difference being kept constant at 50 volts.

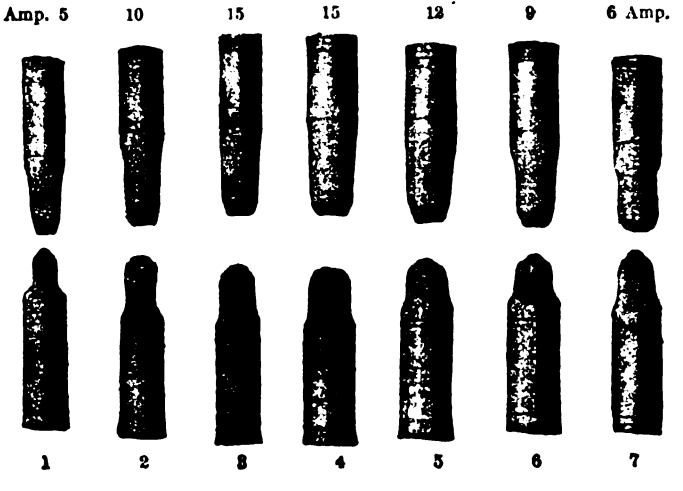

Fig. 14.—Form of the carbon points; constant potential = 50 volts.

Fig. 14 shows the form of the points with different currents. Nos. 1, 2 and 3 are pencils of the brand C., and 4, 5, 6 and 7 of the type E. Examining the first three pencils, we see that with 5 amperes, there is a tendency to form a "mushroom" on the lower or negative carbon; the latter is eaten away considerably just below the tip. With 10 amperes this tendency is not at all marked, and at 15 almost inappreciable. Glancing at the upper or positive carbons, it appears that the smaller the current, the more nearly does the positive pencil burn to a point; that is, the smaller the diameter of the crater. But though the width of the crater is less in the case of low currents than with high, the depth of the former is correspondingly greater. The photographs do not bring out this point, but an inspection of the tip of the lower carbon gives a clue to the facts. Note that with small currents the negative electrode terminates in a pointed, sometimes globular projection. As has been stated before, th s tip becomes less noticeable with increase of current, a fact which is brought out by inspecting Nos. 7, 6, 5 and 4 (Fig. 14). In No. 4, burned at 15 amperes, the end of the lower carbon is blunted; the depth of the crater in the upper was practically zero. In Nos. 5, 6 and 7, burned at 12, 9 and 6 amperes respectively, the depth of the crater increases as the current diminishes. With high currents, the carbon is disintegrated to a greater distance above the point than with low.

Fig. 15 shows the form of the carbon points when the latter are burned with constant current = 10 amperes. The range in potential difference was from 40 to 60 volts. Just as the peculiar burning of the tip distinguishes a pencil fed by a low from one burned at a

*. M. Gérard: Candle-Power of Arc Lamps, *Centralblatt für Electrotechnik*.

Digitized by Google

high current, so the form of the carbon-point differs in the case of a pencil burned with low voltage than with high. In Nos. 1, 2, 3, 4, and 5 (Fig. 15), the gradual change in the formation, from a sharp projection at 40 volts to a blunt end at 60 volts, is noticeable. The "mushroom" which invariably forms in carbons burned at a low current and high voltage, is absent when the pencils are burned at high current and low voltage.* In the former instance the thin neck of the "mushroom" often breaks, thus arresting the current and extinguishing the arc. In the latter case the end of the carbon is prone to so burn away as to leave a concave outline. (See No. 1, Fig. 14.) At 40 volts the depth of the crater measured ·051 inch. At 60 volts the crater disappeared; the carbons also "flamed" at this high voltage.

With a given current there is for every brand of carbon a certain voltage, above which, if the pencil be burned, "flaming" will result. A simple trial is sufficient to determine this critical point.† Again, there is a voltage below which, if the carbon be burned, "hissing" takes place. With perfectly centred carbons there is no difficulty in ascertaining the latter point. Careful observation of the arc shows that when the tension is too high for a given carbon the walls of the crater break away, allowing the arc to play on the outside surface of the carbon. This action is always accompanied by a flame, which shoots from the negative carbon. On placing the negative pencil above and the positive below, the flame shoots down. With soft-cored carbons, well centred, one cause of flaming—namely, liability of the arc to play laterally—is obviated; and if the pencils be burned with the proper current and voltage, there seems to be no reason why this disagreeable feature of the arc-lamp should not be entirely overcome. There is not so much liability to "hiss" in a high-tension system as in a low, for from the formation of the carbon-points, when the pencils are burned in commercial low-tension lamps, it appears that the negative carbon terminates in a small mushroom-button. The breaking of this

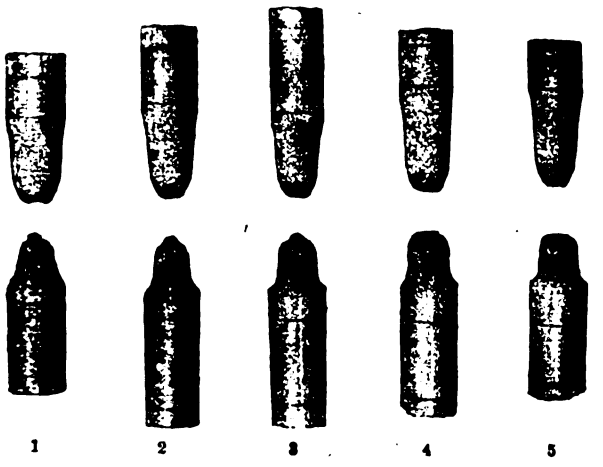

FIG. 15.—Form of the carbon points; constant current = 10 amperes.

pellicle of carbon, and the consequent action of the lamp mechanism to reduce the rise in potential due to the rupture, invariably result in the "hissing" of the arc. Most of the irregularities in the action of arc-lamps probably result more from the unsuitableness of the carbon than from defects in the lamp-mechanism or changes in the strength of the current and potential difference in the line. The remedy lies with the carbon manufacturer. A careful study of the relation between the microscopical structure of the pencil and the action of the latter in a given case would be likely to bear fruitful results. Of course the field for experimentation is large, but the improvements which must necessarily follow conscientious research will undoubtedly be of great scientific as well as commercial value. In the present state of the art of carbon-manufacture, it is the central-station manager who must exercise great discrimination in the selection of arc-light pencils for his plant. Mr. E. F. Peck has recently shown how a "comparative test of the best known carbons in the market" resulted in "a saving of 64·73 electrical horse-power in a station burning a thousand arc-lamps."‡ But there is no reason why the carbon manufacturer, given the condition of a lighting system as regards current, tension, required light and life of pencils, &c.—should not be able to produce a carbon specially adapted to the needs of that system. When the root of existing defects is thus struck at, the solution of the arc-light carbon problem will be at hand.

The experiments published in this paper were made under the direction of Professor Edward L. Nichols, in the laboratory of Cornell University. The writer is indebted to Mr. A. B. Levy, P.G., for valuable assistance in the work.

* When the carbon is impure and contains a large amount of silica, the latter is often deposited in the form of a glass bead on the point of the negative pencil. The "mushroom" alluded to in the text does not refer to this deposition.

THE ELECTRIC CURRENT AS A TRACTION INCREASER.*

BY ELIAS E. RIES.

Within the past three or four months a number of articles have been published in the electrical journals purporting to show, some theoretically and others by experiment, that the passage of an electric current between a driving wheel and rail could have no effect in increasing the traction or coefficient of friction between the two surfaces in contact, and that if the current had any influence at all upon the friction it could only act to reduce the traction instead of increasing it. As the writer was probably the first to call general attention to the importance of increasing tractive adhesion by the direct action of the electric current, and the first to point out the laws bearing upon this subject, as determined by experiments made by him several years ago for that purpose, it seems fitting that he should reply to these articles.

It appears to have been taken for granted by many persons, probably because the phenomena of increased traction were first observed in the operation of electric railway motors, that the mere use of the track rails as the return conductor in an electric railway system is all that is necessary in order to ensure increased adhesion between the motor wheels and the rails. This is by no means the case, as the result is entirely dependent upon the nature of the current employed and the circumstances under which it is permitted to act. As a matter of fact, the conditions existing on single-trolley railways, as at present operated, are not such as to be favourable to the production of increased traction; and although a certain amount of increase in adhesion occasionally manifests itself, it is not such as to be relied upon with any regularity or certainty, and is due, as will hereafter appear, to causes entirely different from those that produce increased traction in cases where a local or independent traction circuit moving with the vehicle is employed, such as embodied in the method of electrically increasing traction devised by the writer.

In my original Paper upon this subject, read before the American Association for the Advancement of Science in August, 1887, the underlying principles and conditions governing the production of increased friction by the action of the electric current were set forth for the first time in the following paragraph:—"Before entering into a description of the means by which this result is produced, and how it is proposed to apply this method practically to railway and other purposes, it may be well to give a general outline of what has so far been determined. These experiments have shown that the coefficient of friction between two conducting surfaces is very much increased by the passage there through of an electric current of *low electromotive force and large volume*, and this is especially noticeable between two *rolling* surfaces in peripheral contact with each other, or between a rolling and a stationary surface, as in the case of a driving wheel running upon a railway rail. This effect increases with the *number of amperes of current* flowing through the circuit of which the two surfaces form part, and does not materially depend upon the electromotive force, so long as the latter is sufficient to overcome the electrical resistance of the circuit. This increase in frictional adhesion is principally noticeable in *iron and steel*, although present in other metallic bodies, and is due to a molecular change in the conducting substances at their point of contact (which is also the point of greatest electrical resistance in the circuit) *caused by the heat developed at that point*. . . . The most economical and efficient results have been obtained by the employment of a transformed alternating current of *extremely low electromotive force, but of very large volume or quantity*, this latter being *variable at will*, so as to obtain different degrees of frictional resistance.

The correctness of the principles originally set forth in the above paragraph have been repeatedly substantiated by subsequent experiments, and it will be seen therefrom that, in order to produce increased traction by the direct action of the electric current, the following conditions must be observed:—1. The current must be of such volume as to produce an appreciable amount of heat at the point or points in contact. 2. The electromotive force must be as low as possible. Experiments made by the writer have shown that a high electromotive force has a tendency to

* From the *Electrical World* (New York).

Digitized by Google

diminish friction, especially if the pressure between the surfaces in contact is a moderate one. 3. The metals in contact should be of iron or steel, as these have the requisite electrical resistance at their contact surfaces, and are of such molecular structure as to permit of a close and intimate union between them under the influence of the current. 4. One or both of the metals should preferably roll upon the surface of the other. This is desirable in the first place, in order to economise current by concentrating the heating effect upon as narrow a line of contact as possible. Furthermore, a rolling motion, where the line of contact moves progressively and uniformly along both surfaces, as in the case of a wheel and rail, where the contact is continually established at new points, requires less current to produce a given tractive effect than in case of sliding friction, where the surfaces move at different rates of speed, and are never in fixed relation to each other for an appreciable length of time.

Let us now see whether or not these conditions have been fulfilled by those who have endeavoured to show that the electric current is incapable of increasing tractive adhesion. We will then look at the matter from a more practical standpoint, and show what the electric current has done, and is capable of doing, in this direction, when properly applied. Prof. Lucian I. Blake, in a Paper recently read before the Kansas Academy of Science, describes and illustrates a number of experiments stated to have been made for the purpose of determining whether an electric current would, as stated, increase the friction between a wheel and rail in electric railways. Four different experiments are described, not one of which even *approaches* the conditions met with in railway practice. In two of these experiments such metals as platinum immersed in flowing mercury and a brass bar sliding upon brass rails were employed! The flat surfaces in frictional contact "varied from one and a-half to three square inches," an amount several times greater than the combined effective area of contact of four ordinary railway car wheels, while the current sent through these surfaces was several times less than that ordinarily used in railway practice, being but one ampere and ten amperes respectively! The two remaining experiments illustrated a case of rolling or skidding friction in which the current used was presumably the same as in the first experiment, "varying from 0 to one ampere." In short, these experiments seem to have been devised for the express purpose of showing "how *not* to do it," since Prof. Blake himself admits in concluding that "the currents employed were not sufficient to produce heating at the surfaces of contact," and adds that "such heating would doubtless produce an increase of the coefficient of friction." Mr. O. T. Crosby has also described some dynamometer tests tending to show that no increase in traction occurs. These tests were made by him with an ordinary single trolley motor car, and consisted in first returning the motor-operating current through the wheels and rails in the usual manner, and then repeating the experiments with the wheels out of circuit. The current employed was varied from 0 to 42 amperes during the experiments, and the electromotive force, though not stated, was probably 500 volts. Unfortunately, the capacity of the dynamometer at Mr. Crosby's disposal was less than that needed to register the ordinary tractive effort of the car on a level track, and he found it necessary to jack up one end of the car so as to *skid* only one pair of wheels and to relieve these of a part of their weight. It will be apparent from what has been said that the conditions under which these tests were made were not only unfavourable to the production of increased traction, but were of such a nature as to bring about the very opposite result.

There seems to be an impression among many persons that the increased traction, if present, must be due in some way to magnetic action. This view of the matter has been taken by Mr. Nelson W. Perry, of Cincinnati, who endeavours to show that no appreciable increase in traction can result from the direct passage of an electric current from wheel to rail, or *vice versâ*, because there would not be sufficient "*attractive*" force produced. It is further stated that the passage of current in this manner could only result in a repellant action between the metals in contact, the author citing, among other things, the action of the electro-motograph in support of his views, and in general denying that increased traction could result by reason of *any* change, molecular or otherwise, caused in the surface of the metals by the action of an electric current, notwithstanding the fact that elsewhere in his communication he admits having witnessed an experimental demonstration in which the current *did* have the effect which he endeavours to prove it *could not* have. It is needless to state that there is not the slightest basis for any of the theoretical conclusions referred to, which probably arise from a misconception of the real actions to which the increased adhesion is due.

We will now consider the part the current plays in the production of increased traction. It has already been said that this phenomenon is directly due to the *heating effect* of the current upon the metals at their point of contact. A certain slight magnetic effect is necessarily also present, but this is so small in the case under consideration that it does not enter to any appreciable extent into the result, and may therefore be neglected. This heating produces a molecular change in the surfaces of the metals, which causes a variation in the coefficient of friction between them; but the nature of this variation and the manner in which the increased adhesion is produced depends upon the nature of the metals and the degree of heat developed at their points of contact. As an illustration of this it may be stated that a moderate current of sufficient strength to cause increased adhesion between iron or steel surfaces will have a lubricating effect upon brass contacts and causes a diminution of the normal friction between them, although with a sufficiently large current the friction may be increased. Experiments have shown that in the case of iron and steel a comparatively slight amount of heat will serve to increase the friction to an appreciable extent, this being due to a slight expansion and elevation of the metal at one or both sides of the normal line of contact. This action is practically spontaneous, the heating effect taking place on the *surfaces* of the metals long before the body of the latter have had time to become sensibly warm. That the particular effect here referred to is due principally, if not entirely, to the heat, and not to the current directly, is proven by experiments made by the writer with a small electric railway model, in which the increased friction continued an appreciable length of time *after* the traction current had been cut off, the wheels of the motor car having been previously heated by the current so as to retain for a time a portion of the heat imparted to them. The friction between driving wheels and rails is considerably increased beyond this point, however, by increasing the current strength so as to produce a still greater local heating of the metals at the point of contact; and this is the method preferred by the writer, and most economically carried out by the use of a closed traction-increasing circuit of low resistance, moving with the vehicle and including the driving wheels and that portion only of the track rails that lie between them. When the current strength is sufficiently augmented the increased traction becomes due to an *incipient welding* of the metals along the line of contact. This action leaves no permanent trace upon the wheels or rails, nor is there any appreciable increase in rolling resistance noticeable. The writer has even increased the current strength so as to produce an actual weld between the wheels and rails, without material injury to either of the rolling surfaces; in some experiments, on overcoming inertia, the metals separating again on the line of the weld, the film of oxide between them. By the employment of a converted alternating current of high periodicity with respect to its volume the heating effect may be confined to the surface of the rails without penetrating into the interior. As a rule, the amount of current needed to produce a given increase in traction is found to be proportionate to the area of the surfaces in contact, and, to a certain extent, to the speed of the driving wheels. The conditions under which increased traction is called for in practice are favourable to the use of a comparatively small amount of electrical energy for this purpose, since it is only in starting heavy loads and in ascending grades, when the rate of speed is much below the normal, that increased adhesion is usually required.

The writer has recently had occasion to construct a small electric motor car and track with which a number of important facts bearing upon this subject have been satisfactorily illustrated. This model is still in existence, and may be seen in successful operation at the writer's office, room 27, Chamber of Commerce Building, Baltimore, at any time. The apparatus in question consists of a small electric railway car having two driving axles insulated from each other and operated by a small electric motor supplied with current through flexible conductors in circuit with a single cell of secondary battery. The driving axles are arranged so that one of several sets of iron or steel driving wheels of different diameters can be placed thereon. The traction increasing current is derived from an independent source, and is varied according to the requirements of the experiment in hand. This current, by means of a second pair of flexible conductors connecting with binding posts on the car, is sent from the forward to the rear driving axles through the intervening driving wheels and track rails, although the arrangement is such that it can be sent directly from one rail to the other across the wheels and axles, thus enabling the terminals of the traction circuit conductors to be attached to the rails at one end of the track instead of being carried by the motor. The weight upon the driving wheels without extra load is about three pounds.

With this apparatus, employing a continuous traction-increasing current derived from one cell of secondary battery, the tractive effect of the motor car was increased considerably over 150 per cent., the car climbing grades of thirty feet to the hundred with perfect ease against the pressure of a spring tending to pull it backwards; whereas, with the same propelling current flowing through the motor, but with the traction circuit open, the car remained spinning at the bottom of a 10 per cent. grade, not having sufficient tractive adhesion to lift its own weight. Upon again closing the traction circuit the car instantly regained its grip upon the rails and shot up the incline until its further upward progress was stopped by the distended spring and cord that secured the car to a post at

Digitized by Google

the lower end of the track, and prevented it from running over the top of the incline. No sparking, flashing, or other visible indication that current was passing between the wheels and rails could be observed in this experiment. There is no mistaking the action of the motor, or the important part the current plays in increasing tractive adhesion. If, while the car is ascending a steep grade, the traction-increasing circuit be opened and then again closed, the car will commence to slip backward, and continue doing so with accelerated speed until the moment the circuit is completed, whereupon its descent will be almost instantly checked, and it will promptly proceed to mount the grade again as if nothing had happened. Among other things, it was shown by this apparatus, as originally predicted, that the traction is not diminished, but (compared with mechanical traction under like conditions) enormously increased when the rails are wet or slippery. The presence of water on the rails seemed to make no difference in traction while the current was passing. With the rails and wheel tires thoroughly *oiled* the car remained stationary with the motor running at the bottom of a 6 per cent. grade. One end of the track was then elevated to form a 25 per cent. grade, and on closing the traction circuit the little car actually climbed up the slippery track as far as the spring would permit without a single idle revolution of the driving wheels! On increasing the traction current by connecting a second cell in series with the first, so as to produce a perceptible and progressive incipient welding between one or more of the wheels and rails, the tractive pull of the car on a level track, as measured by a standard spring balance dynamometer, was rapidly increased from six ounces, the normal pull without traction current, to 31 ounces with the current, *an increase of over 500 per cent.!* Were it not for the fact that at this point the load and the tractive adhesion exceeded the maximum power developed by the little motor, the increased traction actually registered would have been much greater. With the same current passing between the wheels and rails the car performed the remarkable feat of ascending without any slip a *50 per cent. grade, part of which was coated with oil!* This experiment has since been witnessed by a number of prominent electricians and engineers, who expressed themselves as astonished beyond measure at the wonderful increase in friction obtained, and the comparatively small amount of electrical energy required to produce it.*

In order to determine some of the conditions bearing upon the application of this system of increasing traction to ordinary railway train service, a series of preliminary experiments upon a large scale were made by the writer nearly a year ago with a locomotive on the Philadelphia and Reading Railroad. These tests were made with a locomotive selected by the railroad company, a "consolidated engine weighing 111,000 pounds (one of the heaviest and most powerful in the service of the road), of which 98,000 pounds, or nearly 50 tons, were distributed over *eight* coupled driving wheels, measuring about 54in. in diameter. The traction current was generated by a special low-tension, direct-connected steam-driving dynamo mounted upon the locomotive, one terminal being connected by a heavy stranded copper cable with the forward and rear pairs of drivers respectively, which were insulated from the frame of the locomotive by special insulated brasses at the boxes and journals, the opposite terminal of the dynamo being connected with the two intermediate pairs of drivers. This arrangement was adopted to avoid interruptions in the circuit at the rail joints, which on this road, as is usually the case elsewhere, were not directly opposite on both rails, but overlapped. The average resistance of the traction circuit with the locomotive at rest measured less than one-hundredth of an ohm, practically all of which was located at the respective points of contact between the wheels and rails. The current could be varied during the different tests by varying the field strength or speed of the dynamo, or both, from about 500 amperes to the maximum output of the machine.

The first experiment was made on a substantially level track, and consisted in coupling the locomotive to a train of 12 loaded coal cars and setting the brakes on these so that the engine could not possibly start the train without continuous slipping, several unsuccessful attempts to do so being made. The dynamo was then started up and the trial repeated with *entire success*, the train being brought under full headway from a position of rest without a single slip of the wheels. This was repeated a number of times, the engineer being instructed to do his utmost to make the wheels slip while the current was flowing, as by suddenly throwing open the throttle to its widest extent with the eccentric lever in its foremost notch, &c., without effect. It was estimated that the load moved by the engine during this test was equivalent to a train of 110 cars!

A number of subsequent tests were made on the Frackville branch of the Reading Railroad, upon a steep mountain grade seven miles in length, averaging 185ft. to the mile, and with numerous sharp and difficult curves. Regular service runs were made over this grade both with and without the current, under conditions as nearly alike as the traffic over the road would permit, with entirely satisfactory results. The official records of the tests show that in nearly every instance the use of the current produced a decided increase in the tractive capacity of the locomotive, and prevented the enormous wear and tear, loss of time and consumption of coal occasioned by the excessive slipping that took place when natural adhesion alone was relied upon. On one occasion the time required to ascend the grade with a load slightly in excess of that usually carried was, without current, 55 minutes, as against 29 minutes with the current flowing, under exactly similar conditions. The amount of coal consumed on the last-named trip was *less than one-half* of that used on the trip without current, by reason of the absence of the rapid exhaust and loss of power consequent upon the slipping of the drivers.

These tests, though made under some disadvantages, were so satisfactory that they are now being continued under conditions and auspices more favourable for carrying out this work. It is estimated that the tractive adhesion of steam locomotives can by this method be increased 25 per cent., and even more in special cases, or where the construction of the locomotive is such as to permit it to utilise a greater increase. This not only means that four locomotives will be enabled to do the work that now requires five, but that longer and heavier trains can be moved, better time made, steeper grades operated, quicker stops effected, inertia more promptly overcome and more fuel saved than by the present methods, and what is perhaps of the greatest importance, without any material increase in the weight upon the drivers or roadbed. These and other advantages are by no means limited to steam locomotion, but apply to electric railway operation with equal or even greater force.

The question will now be probably asked: "Are the conditions existing on electric railways employing the rails as a return conductor for the propelling current such as render this current a factor in increasing the traction, and, if so, to what extent?" Before answering this question let us briefly review these conditions. In the early days of electric railways the potential difference under which the motors were operated was very small, in some cases as low as 120 volts, and the currents correspondingly large. The track rails were usually of some obsolete light-weight T pattern that had done more or less service on some suburban horse railway line, and the bearing surface of which was curved to such an extent that the driving-wheel contact amounted barely to a point. Under these circumstances a useful amount of increased traction was obtainable, especially in starting the motor on a grade, when the flow of current was unusually heavy. On "single trolley" railways, as at present operated, under a potential difference of 500 volts, the currents employed are not sufficiently large to produce increased traction by the *direct heating* of the metals in contact, except when, as sometimes happens, the tread of the wheel runs upon an exceedingly narrow portion of the rail surface, and even this effect is largely if not entirely counteracted by the high E.M.F. of the current. However, a certain amount of increased traction may be, and often is, *indirectly* produced by the current on single trolley railways. This occurs when the contact between the wheels and rails is temporarily interrupted at more or less frequent intervals by particles of sand or other foreign matter on the rails, thereby giving rise to small electric arcs and producing the "flashing" noticed under these conditions. The heat generated by these arcs is, in many cases, sufficient to soften the metal and to cause an actual fusing or welding action between the surfaces of the wheels and rails when they again meet beyond the grain of sand or other obstruction, the latter being sometimes vitrified or decomposed by the arc, or embedded in the heated metal. As the car moves forward, the arc, which is originally sprung behind the obstruction, advances along the wheel and rail to a point in front of it, and the points of the metal thus heated, approaching each other, unite under pressure and almost instantly cool, extinguishing the arc in so doing and producing a more or less perfect weld at the points of contact to which the increased traction is due. The welds thus formed are again broken, during the separation of the wheel and rail surfaces, on their line of least resistance, which is generally that corresponding to the original surfaces, because of the film of oxide and other impurities usually found between the fused metals, and which in most instances prevents a homogeneous weld.

From this it will be seen that notwithstanding the small volume of the current on single trolley railways an appreciable amount of increased traction may manifest itself by reason of the comparatively high electromotive force, producing a change in the action of the current. The use, for example, of a moderate amount of sand in

* It appears that the presence of water or oil upon the rails, as shown by these experiments, has a tendency to confine the passing current to a much narrower and smaller area of contact between the wheels and rails, thereby enabling a given current to produce a much greater heating effect at the very point where it is wanted. In other words, the weight upon the drivers is sufficient to "squeeze out" whatever oil may lie directly under the mathematical line of contact; but the film of oil or water at either side of this line offers sufficient resistance to the low-tension current to confine the passage of the traction current to the exceedingly narrow portion of the wheel surface in actual metallic contact with the rail. Thus, what has always been a decided disadvantage to mechanical traction is, or may be, utilised in a most important manner in increasing traction electrically.

Digitized by Google

conjunction with the current on grades of more than usual steepness will serve to increase the adhesion both mechanically and electrically to a certain extent; but this plan is not nearly as efficient, economical or reliable, leaving out for the present the question of its advisability, as the employment of a current of lower voltage and larger volume for the direct and uniform heating of the contact surfaces.

It may be stated in conclusion that, while it is possible to obtain a certain appreciable percentage of increased traction on electric railways in which the propelling current is returned through the wheels and track rails, and while in some few cases a slight increase is necessarily present as a function of the propelling current, yet the conditions under which such roads are usually operated are not favourable to the production of such increased traction. Numerous experiments made by the writer have shown that the most satisfactory and economical method of employing the electric current as a traction increaser, whether on steam or electric railways, is to establish an independent low-resistance circuit, including the driving wheels and so much of the track rails as lie between them, and to charge this circuit with a low-tension traction current capable of producing the desired heating effect. As this circuit is entirely independent of, even though it may be derived from, the motive power of the vehicle, the amount of increased traction can be regulated without regard to the speed of the motor, and can also be used on down grades to assist the brakes in stopping the car. The increase in the adhesion on single trolley roads under the most favourable conditions is limited by the low heating effect of the propelling current, whereas in the case of the independent traction circuit there is practically *no* limit to the amount of increased adhesion obtainable, since this adhesion may be increased to such an extent as to actually weld or "freeze" the driving wheels to the rails.

THE TREATMENT, REGULATION, AND CONTROL OF ELECTRIC SUPPLY BY THE LEGISLATURE AND THE BOARD OF TRADE.

The following is the authorised abstract of the discussion on Major Cardew's Paper :—

Mr. CROMPTON expressed his opinion that the electric lighting industries had suffered considerably from over-legislation, and he disagreed *in toto* with Major Cardew's statement that the Act of 1882 did not do the amount of harm generally attributed to it. He admitted that over speculation in electric light patents had a depressing effect ; but he himself could vouch for the fact that the Act of 1882 prevented a large central station in which he was interested from being carried out. Had this been proceeded with, experience for which we had now to go to America would have been gained first hand. Unnecessary legislation had also caused immature and incomplete schemes to be brought forward, and seriously interfered with the natural development of the industry. The question of sites for stations had been placed in an unsatisfactory condition ; for under present circumstances it was necessary to keep their positions secret, and this necessity caused hurried designs and workmanship, as well as increased cost. He firmly believed that the old method of obtaining private Bills, as for gas works, would have been far more satisfactory to all than the present system of Provisional Orders ; and he felt quite sure that the gas works clauses could have been easily modified to make them applicable to electric lighting stations. Whilst fully admitting that the Board of Trade had done all in its power to make the Acts workable, and that the thanks of all interested were due to the officials for the great efforts they had made, he could not help thinking that the tendency of modern legislation was to interfere too much, and to show people how to do their own work. The case quoted by Major Cardew as to consumers being entitled to the choice of two pressures, one about half the other, was, in his opinion, one of undue interference ; for it was quite as much a pure commercial question as whether a grocer should make up his tea in pound or half-pound packages. Another case of injustice occurs where the supplier is required to provide larger terminals when a greater supply is needed by a consumer than he originally estimated.

Mr. G. OFFER endorsed Mr. Crompton's remarks about the Board of Trade officials being always anxious and ready to deal practically with the questions which arose. He also thought that we suffered from over-legislation. One serious defect of the present system was the inordinate length of time required to obtain a Provisional Order ; for the Preliminary Order must be applied for in July, whilst the confirmation of the Order cannot be granted until August in the following year. Should an unexpected dissolution of Parliament occur in the interval, the consequences would be very serious to the applicants. He submitted that a great improvement might be effected by materially shortening the time between the application for, and confirmation of, Provisional Orders ; or, better still, by avoiding the necessity of obtaining confirmation bills. As this confirmation is not required for licences, he thought Orders might be treated similarly. As to the position of Local Authorities being more favourable than that of private companies under the Acts, he thought this a distinct advantage, for it would facilitate procuration of capital for carrying out lighting schemes, whilst private companies would obtain the work without incurring all the risk. The appointment of electrical inspectors and consulting engineers were points on which he believed Local Authorities were somewhat confused ; and to show the state of some minds on the subject, he cited a case in which a Local Authority wished to appoint an inspector, but stipulated that his salary was to be paid by the undertakers.

Mr. J. SHOOLBRED thanked Major Cardew for the concise account of Provisional Orders which he had given to the Institution. There were one or two points to which he desired to direct attention in connection with such Orders, viz., the necessity for bye-laws and the question of overhead wires. Bye-laws, he said, were becoming more and more important for the protection of undertakers rather than for customers ; this, he was glad to see, had been partly recognised by the Board of Trade in granting access to consumers' premises in some cases, but facilities for examination of fittings, &c., were still required, for vexatious customers can and do throw serious difficulties in the way of undertakers. As regards overhead wires, he pointed out that considerable complication had been introduced by the Board of Trade legalising them to some extent, for it would lead to unfair competition. Many overhead wires had been erected without statutory powers, and if these were permitted to remain, the companies or persons in possession, although they did an illegal act in erecting them, would be allowed a great advantage over another law-abiding company in the same district, which was compelled to put its wires underground. Referring to meters, he asked if any had been certified, and whether steps had been taken towards the formation of branch offices at which meter tests could be carried out. In the event of such offices being established, he wished to know if they would be representative of the central office. Speaking of the clauses in the new model Provisional Order relating to the pressure being declared at the customers' terminals, he pointed out that in some cases a consumer may declare a pressure which it would be practically impossible for the undertakers to supply.

The discussion was adjourned to the 22nd inst.

THURSDAY, May 22nd.

Mr. A. A. CURTIS HAYWARD remarked that Major Cardew's paper touched lightly on the appointment of electric inspectors. He considered the vesting of such appointments for the Metropolitan district in the London County Council a regrettable incident, and was glad to note that in future orders the right of appointment would be vested in the Board of Trade. The appointments were, he said, at present very important, for the public had been somewhat alarmed by the sensational accounts of accidents in America. The knowledge that properly qualified inspectors were to be appointed would tend to restore confidence and give great satisfaction to the community. His opinion as to the future importance of electric inspectors did not coincide with that of Major Cardew, for he believed theirs would be a case of degeneration rather than one of development. He could not agree with Mr. Crompton about over-legislation, and thought the latter gentleman overstated the case when he said that the gasworks clauses might have been easily modified to cover electric supply. A real need for a special Act existed ; for there were many subjects in electric supply, such as overhead wires, &c., which were quite foreign to gas distribution.

Mr. EMILE GARCKE said that he was not prepared to discuss the details of the regulations in the face of Major Cardew's statement that criticism from even a high electrical authority might be erroneous. He would rather confine himself to the historical facts. The parliamentary history of electric lighting was unique, and the rapid changes that had taken place in the industry were phenomenal. The first Select Committee (he said) was appointed in 1879, when the commercial possibility of incandescent lighting was unknown. Its fair report encouraged contracting firms to promote Bills in Parliament. In the spring of 1882 another Select Committee was appointed, and in the same year the memorable Act of 1882 passed. Although its results were lamentable in one respect, he thought it not an unmitigated evil. After detailing the various attempts to remedy the defects of that legislation resulting in the Act of 1888, he pointed out that no time had been lost, and that progress had been comparatively rapid. He laid great stress on the exceptional character of the legislation even of the amended Act, saying that no other industry had ever been placed under such adverse conditions, excepting, perhaps, by the Tramways Acts, but even this was much more favourable to the contractors than the Electric Lighting Act of 1888. The exceptional character arose from the fact that Parliament refused to put electric lighting Corporations on anything like the same footing as gas companies, and thus the former had to compete on very unfavourable terms. It was in the power of the gas companies by foregoing their dividends for a year or two to completely crush electric companies ; for in addition to their power to pay accumulative dividends they had the advantage of practically perpetual tenure, whilst the electric companies were limited to 42 years. As regards local authorities, he complained that according to present regulations it was in their power to stifle electric lighting, and as many of them were largely interested in gas, he argued that it was not right that the electric companies should be placed in such a difficult position. To show how vexatious local authorities may be, he quoted a case of a central station established in the early days of electric lighting. The work was carried out satisfactorily by overhead wires until such time as regulations were issued by the Board of Trade stating that all wires must be put underground. In the face of the 21 years' purchase clause it was financially impossible to comply with the regulations. When the amended Act was passed in 1888, the Company applied for a Provisional Order, but were opposed by the Local Authority, which was at that time negotiating for the purchase of gas works. He was not aware that any other kind of vested interests had been similarly treated.

Mr. K. L. MURRAY expressed the great pleasure he experienced in hearing the discussion on such an important subject, and at being in the presence of so many eminent persons on whose sayings and doings they in Australia were so largely dependent. In Victoria, he said, they had no

Digitized by Google

Acts of Parliament or regulations to control electric supply, and until recently they had no rules. Last year, however, the Victorian Institute of Engineers had drawn up a set of rules based largely on those issued by this Institution and by the insurance companies. He did not agree with those who said that electric supply needed no regulation; for defective workmanship should be carefully guarded against, and for this object rules or regulations were necessary. An Act of Parliament, he said, was now expected in Victoria, and the present discussion would aid in framing the Bill. A knowledge of what to avoid as well as what to do might, he hoped, lead to a model Act, from which, perhaps, the mother country might copy with advantage.

Captain ROWAN said that in Australasia, where he had been engaged in introducing electric lighting, difficulties arose from want of legislation. No public body had power to give authority to lay mains or to erect overhead wires, &c., and in consequence matters had come to a deadlock. Mr. Murray, he said, had told them that legislation had been delayed until it was known what was to be done here. He hoped that the present discussion would materially assist those on the opposite side of the globe to hit the happy mean whereby public safety might be assured without the industry being hampered.

Mr. H. HUMAN disagreed with what Mr. Crompton said about the injustice of compulsory supply at either of two pressures, and pointed out that a grocer who made up his tea or sugar in pound or half-pound packages had not a monopoly granted to him for 42 years. In his opinion there was no particular hardship to the undertakers in the regulation, whilst it was a distinct boon to customers. He thought Mr. Crompton, in his remarks about the gas and water companies, had overlooked the fact that they had been sources of complaints for years. His comparison of electricity with gas and water was not legitimate; for in the former case, where such a subtle agent as electricity was dealt with, consumers were much more at the mercy of undertakers. In America, he said, where the industry had not been hampered by legislation, there had been so many accidents and fires that the public were now appealing for control, and the wish had been expressed that a body analogous to our Board of Trade was in existence there. Speaking of safety devices he wished to see their use made compulsory where the pressure exceeded 1,000 volts. In conclusion, he said that the Acts of Parliament, if harsh, were necessary; and he hoped that those who advised the Board of Trade would hold the scales equally between consumer and undertaker.

Mr. A. SIEMENS said it should be borne in mind that the objects of the legislation were twofold: first, to empower electric supply companies, &c., to lay mains in the public streets, and conduct the business of supply in a manner recognised by law; second, to recover charges for supply made to consumers. Both these aims were intended to confer powers on companies which otherwise they could not possess. Originally, he said, the Board of Trade had power to grant Provisional Orders without the consent of the Local Authority, but in the later development neither licences nor Orders could be granted without such consent being first obtained. In contradistinction to the case quoted by Mr. Garcke, he said that in one town a company had started a station in spite of the fact that the Local Authority had obtained a Provisional Order; subsequently, the Company wanted to claim compensation for loss of vested interests. There was only one point in Major Cardew's Paper which he considered disputable, and that referred to testing stations at pillar boxes. In his opinion they were unnecessary, for a recording instrument in the central station should fulfil all requirements. If, however, the Local Authority wanted a separate station, that could be easily arranged.

Mr. J. S. FAIRFAX hoped that no hard and fast line would be laid down as regarded the kind of instrument to be used at testing stations. In his opinion the paragraph in Major Cardew's Paper referred to some kind of dial arrangement, but he thought one on the deposition principle might be more correct.

Mr. ED. C. DE SEGUNDO did not agree with Mr. Crompton about the Board of Trade having gone too far; in fact, he thought it had not gone far enough as regards protection of the public by making regulations for insulation tests. He knew a case where a 1,000-volt circuit was tested at 100 volts, and he pointed out that to test a steam boiler intended to work at 100lb., with water pressure at 10lb., would be considered ridiculous. The testing of house wires was also very important, for in one case he was assured that there was no defect in the insulation, for in the contractor's tests no indication of a leak was obtained. On applying Evershed's ohmmeter with about 100 volts a dead earth was indicated.

Mr. MORDEY, in referring to the question of safety devices, said it was time the subject was settled. The method of earthing the secondary was, in his opinion, perfectly safe. Great opposition had been made, particularly by the insurance companies, to its adoption; but the reasons for such objections were not forthcoming. As far as he could see there was no danger whatever with the secondary volts at 100, for by earthing the middle of the secondary the greatest difference of potential possible was 50 volts. Besides, the method had also the advantage of weeding out all rotten installations. They had used the method on the Continent, and found it quite successful. The fuses, however, often go, owing to persons inserting penknives, &c., into the switches for the object of obtaining agreeable medical shocks. As regards the Cardew device, he pointed out that its cost was not an unimportant item; moreover, it was automatic and might not go off, and generally the fewer automatic arrangements there were about an installation the safer it was.

Mr. A. P. TROTTER inquired what excess of current was required to let the fuses off, to which Mr. Mordey replied that about 20 per cent. above the normal was the ordinary average. In his opinion such currents could not give rise to fires.

Dr. FLEMING asked what occurred in the case of an earthed secondary, when the primary was also earthed! In Italy, where they had had considerable experience in alternate-current distribution, the tendency was in the opposite direction, for the greatest care was taken to perfectly insulate both primary and secondary circuits. He himself had used an earthed secondary at the Inventions Exhibition, and had found no difficulty, but he wished to ask Mr. Mordey what his experience was.

Mr. MORDEY said that no difficulties had been met with.

Major CARDEW, in reply, pointed out that the Board of Trade could not adjust or redress any wrongs, for such changes in the law must be made by Parliament. With respect to the declaration of pressure at consumers' terminals, he said that was rendered necessary by the introduction of transformers, for it was more difficult in such cases to know the fall of pressure in the distributing mains than in continuous-current distribution. He then read the following draft, which is to be inserted in the new Model Orders:—"Before commencing to give a supply of energy to any consumer the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumers' terminals shall not, except by agreement, be greater than 115 volts, or less than 45 volts, if continuous, or the equivalents thereof respectively, if alternating, and shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In distribution on the three-wire system, the central terminal shall, for the purposes of this regulation, be considered to form a pair with either of the outer terminals, and similarly for multiple wire systems; and, in the case of a transformation of energy on the consumer's premises, the undertakers shall give the consumer the choice of a supply at either of two pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure." In drafting this clause, he said, advantage had been taken of the flexibility of the transformer system, in the interest of consumers. Mr. Shoolbred's questions with regard to meters were answered in the Paper itself; for he would there see that they were to be certified by a local inspector, and be of a pattern approved by the Board of Trade. Mr. Murray's remarks about contacts between telephone and electric light wires needed careful consideration, for this was one of the chief sources of trouble and danger where high pressures were used. To Mr. Human he pointed out that the issue of a Provisional Order conferred no monopoly whatever. In reply to Mr. Siemens, he could not say why the change respecting the consent of local authorities had been made by Parliament. Such, however, was the case; and the Board of Trade could not dispense with that consent, except in very special cases. As regards testing stations, he thought the arrangement he had suggested would be more satisfactory to the general public than the use of pilot wires and instruments fitted in central stations. To Mr. Fairfax he explained that the reference to dial instruments in pillar boxes was intended for indicating, and not for recording instruments. Speaking of safety devices, Major Cardew said the plan of earthing the secondary got rid of some defects when the earth connection was substantial, but he thought the fire risks were increased by such a procedure. He had heard of fires being caused through a small leakage current having gradually charred wood, and ultimately set it alight. The apparatus bearing his name was, he said, admittedly automatic, but its action depended only on gravity and electrostatic attraction, and neither of these were likely to alter.

LONDON CHAMBER OF COMMERCE.

Meeting of the Electrical Trades Section Committee.

A meeting of the Committee of the Electrical Trades Section of the London Chamber of Commerce was held on the 16th inst., at the offices, Botolph House, Eastcheap, under the presidency of Mr. R. E. Crompton.

The SECRETARY (Mr. Kenric B. Murray) having read the minutes of the last meeting,

The CHAIRMAN stated that the first subject on the agenda paper was to consider the continuation of the correspondent's appointment, salary, &c.; and the only question was, whether this appointment should be continued for another year, with the arrangement as to salary, &c., remaining. Mr. Trotter's appointment had taken an enormous amount of work off his (the Chairman's) shoulders, and had justified the expenditure that had been incurred.

In answer to a question,

Mr. MURRAY stated that it was arranged that half of the salary to Mr. Trotter should be paid by the Chamber, and half by the Section.

After some discussion, a resolution was passed, on the motion of Mr. S. Sharp, seconded by Mr. G. Binswanger, to the effect that a circular should be sent out asking for a subscription of 10s. 6d. per member of the Section towards the amount of the correspondent's salary for the past and the current year.

Major FLOOD-PAGE thought it would be a good thing for the Section to have a small fund in hand to meet such expenses.

Mr. MUSGRAVE HEAPHY afterwards proposed, and Major FLOOD-PAGE seconded, a resolution to the effect that the Committee recommend the continuation of the appointment of the correspondent for another year, "provided that the Council of the Chamber of Commerce continue to supply their half of the salary, and provided that the balance of the salary be obtained by subscriptions among the members or from the guarantors."

Mr. TROTTER, who had preferred to be in an adjoining room pending the discussion of the question of his reappointment, was then invited to join the meeting; and on being informed of the resolution that had been passed, expressed his readiness to again serve the Committee as before, provided that the appointment might be dropped, or that he might retire, on due reasonable notice, if his own work should so increase as to render such a course necessary.

Digitized by Google

The Committee then proceeded to discuss the next matter on the agenda paper—"The action of the Board of Trade in regard to overhead wires."

The CHAIRMAN observed that as the matter concerned him personally and others a great deal, Mr. Wharton would, perhaps, state what was being done.

Mr. C. J. WHARTON said he thought it would be best for the Chairman to state what had occurred, and then suggestions might afterwards be made by those present.

The CHAIRMAN: Last year the Board of Trade issued a set of rules to regulate the use of overhead wires, and these rules were submitted to a Committee of the Institution of Electrical Engineers. The Chamber of Commerce attempted to have a voice in the matter, but they were rather late in the day, and were not listened to. He was one of the Committee of the Institution, and, therefore, he could not, without a breach of confidence, tell the meeting what had gone on in that committee further than this, which he thought was no breach of confidence—that the particular rule he was going to speak of was not much discussed, and was, in fact, thought very little of. In fact, they had not specimens before them of the cables which the rule was meant to refer to, and they had not presumed that the Board of Trade rule would make an electrical cable into a "pudding," such as the one now in front of him; and at the time, therefore, no one raised any objection to the rule. They fully imagined that Major Cardew had seen cables himself, and knew what they were before he made the rule. That, however, appeared not to have been the case. The rules in question had been issued for some months. There were a large number of installations using overhead wires, and these were now required to be brought into accord with the regulation. Rule No. 9 was as follows: "Every high-pressure aerial conductor must be continuously insulated with a durable and efficient material, to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation must not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. This insulation must be further efficiently protected on the outside against injury or removal by abrasion. If this protection be wholly or partly metallic it must be efficiently connected to earth, so, however, as not to cause undue disturbance to other electric lines or works by electrostatic induction or otherwise." Now this rule produced an extraordinary monstrosity for a small wire, and a cable was produced which was totally unsuited to the purpose intended. He had mentioned his view of the matter to Major Cardew, who replied that the rules of the Board of Trade were not like the laws of the Medes and Persians, and that they might be altered; but that the best thing that could be done would be for his Company to get samples of cable, and that they should then be tested, but in a proper way—tested on the living *experimenta*, as he had himself said in correspondence with the Board of Trade. His Company had put up overhead wires at Chelmsford, and the Board of Trade informed them that they were not in accord—and they were not—with the Board's rules, and that they must put up another description, which the speaker exhibited to the meeting. They replied that they could not do so. Then Major Cardew suggested that they should have three cables made—one exactly in accord with the regulations, one exactly what they thought sufficient, and one made midway between the two. These cables were made and experiments were carried out with them in the presence of Major Cardew. The result of the experiment was to show that as far as insulating qualities were concerned, the thin cable was as good as the other. After standing all the tests satisfactorily, and all of them believing that Major Cardew had been thoroughly convinced, they received a letter from that gentleman to say that the Board of Trade saw no reason to amend their rules. They were, therefore, met with a positive blank refusal to consider a matter which had really never been considered. The consequence had been that four or five gentlemen more immediately concerned had met together and had proposed to memorialise the Board of Trade, pointing out the extreme injustice of this decision, and how it was likely to injure the interests of the trade as a whole, and further suggesting that the Board of Trade might re-examine the circumstances and inquire into the matter. The question was of such universal interest to the trade that they had thought it right to bring it before them at that meeting, so that others might join them in their action if they wished to do so. It was a subject that was of supreme importance, and was the first matter that had really touched their pockets to a very serious extent. He believed that both to the Brush Company, Mr. Wharton's Company, and his (the speaker's) Company, it would make a difference of some thousands of pounds in work already done, and it was practically prohibitory of work in the future. It affected villages, small country towns, and places where there was a quantity of electric lighting extending over large areas.

Mr. TROTTER inquired how many electrical engineers or contractors were on the Committee that were technically consulted about the rules in question?

The CHAIRMAN: Two; Mr. Siemens and himself; and, frankly, they did not see how the rule quoted would affect them.

Mr. EMILE GARCKE suggested the advisability of their passing a resolution urging the Board of Trade to reconsider their determination; and he thought that if a copy of such resolution were sent to the Board of Trade it would have more effect than the memorial to which the Chairman had referred.

Major FLOOD-PAGE observed that the Chairman had said that the Board of Trade proposed to insist on the trade providing a cable which would cost thousands of pounds more than the older one, and be much less efficient. If that were so a question might be asked in the House of Commons (which could be easily managed) as to whether, before determining these questions, the adviser of the Board of Trade had had any practical experience of the carrying out of these things.

The CHAIRMAN said he had wires up now which he knew were not good, and he had, therefore, desired to put up some of the thin wire exhibited to the meeting. He had, however, been forbidden to do so.

Major FLOOD-PAGE proposed the following resolution:—"That this meeting of the Electrical Trades Section of the London Chamber of Commerce, feeling that if the Board of Trade insist upon their decision with regard to cables, as announced in their letter of the 30th ult., to Messrs. Crompton and Co., it will be seriously detrimental to the interests of the electrical trade, without providing additional protection to the public, earnestly solicits the Board of Trade to give their favourable reconsideration to Articles 9 and 12 of the rules and regulations for overhead wires, with a view to this decision being modified."

Mr. R. S. ERSKINE seconded the motion, which was carried unanimously.

Major FLOOD-PAGE said he thought they were hardly enough before the public, and he thought that the time had come when they might derive some advantage from a monthly *resumé* as to the condition of the electrical trade. They knew, for instance, that bullion merchants periodically informed *The Times* of the position of their trade; and the railway companies published their traffic returns weekly. He thought that the time had arrived when the electrical trade should publish similar information, which would be obtained from the various branches of the trade. No names would be published, the idea simply being that those interested might see periodically what was the value of the electrical trade in the United Kingdom. Every Monday morning particularly, he believed, *The Times* published a great deal of this kind of information, showing the position of various trades throughout the country. If similar returns affecting the electrical trade were forwarded to Mr. Trotter, that gentleman would be able to work up a summary, giving the information in question; and he thought that if such information were published, their trade might have a little more weight.

The CHAIRMAN said he thought the idea an excellent one, and the only point was how to give it effect.

Major FLOOD-PAGE said that this would require consideration. It was decided to form a small committee to consider the subject, and bring it forward at another meeting, the committee appointed being Major Flood-Page, Mr. Garcké, and Mr. Sharp.

The CHAIRMAN then read the following letter, which was forwarded to Mr. Murray on the 11th inst. by Mr. Garcké, Managing Director of the Brush Electrical Engineering Company (Limited):—

"Dear Sir: I have received your letter of the 7th instant. I do not know what there is on the agenda; but there is one matter which is coming prominently before us, and with regard to which I have written to Mr. Trotter; it is the question of whether contracting firms can come to any unanimity as to the terms upon which they should tender to local authorities who hold provisional orders. You will, no doubt, hear from Mr. Trotter as to whether he thinks there is any use putting this matter on the agenda, in which case I shall be happy to bring it forward."

Mr. TROTTER pointed out that the letter was received on the same day on which the notice of the meeting was sent out, and was therefore too late to be included in the agenda.

Mr. GARCKE stated that the matter arose out of the large number of Provisional Orders that were being obtained by Local Authorities. He thought that the terms upon which they should tender to Local Authorities would be a large question with manufacturers, and that it would be desirable if contractors could among themselves agree on the general lines on which this class of work should be done. He thought that if provincial authorities offered Orders, they should go a further step themselves, and do the work for which they had obtained powers.

In the discussion which followed, instances were given showing the onerous nature of the conditions sought to be imposed upon manufacturers by certain provincial authorities. In several cases the specifications had been returned by firms who had proposed to tender for this work, but who were compelled to decline to entertain the exorbitant demands and conditions which were imposed. It was suggested that a meeting of electrical manufacturers and contractors might be convened to consider the subject.

Mr. GARCKE observed that it was really a very large question in view of the attitude of the Board of Trade in encouraging provincial authorities to do the work.

Eventually a resolution was passed, on the motion of Mr. GARCKE, seconded by Mr. WHARTON, referring the question to the Committee of Electrical Manufacturers and Contractors.

The CHAIRMAN then expressed regret at having to announce that Lord Crawford had written to state that on account of ill health he did not think that he could retain the position of Deputy-Chairman of the Section. A letter had also been received from Mr. Weaver (who had been asked to serve on the Telegraph Committee) stating that the condition of his health would not permit him to undertake any other engagements at present.

The Insumgraph.—This is an instrument which by the aid of electric currents presents at a predetermined time a clear space of paper for signatures at an opening in a suitable desk, and at the end of the time of grace allowed moves it past the opening. The tell-tale and time-checking systems at present in use, owing to the fact that the necessary signals are made by electric currents set in motion by discs, or plugs, or press buttons, fail to ensure that the proper individual is actually performing his rounds. The insumgraph, however, by making an autograph necessary greatly diminishes the possibilities of fraud

CHARLESWORTH, HALL, & CO.'S PROJECTOR PLANT.

The annexed engraving (Fig. 1) shows one of a number of Search Light Projectors, specially constructed by Messrs. Charlesworth, Hall, and Co., Oldham, for use on small vessels in the night navigation of rivers, canals, and narrow channels. The projector barrel

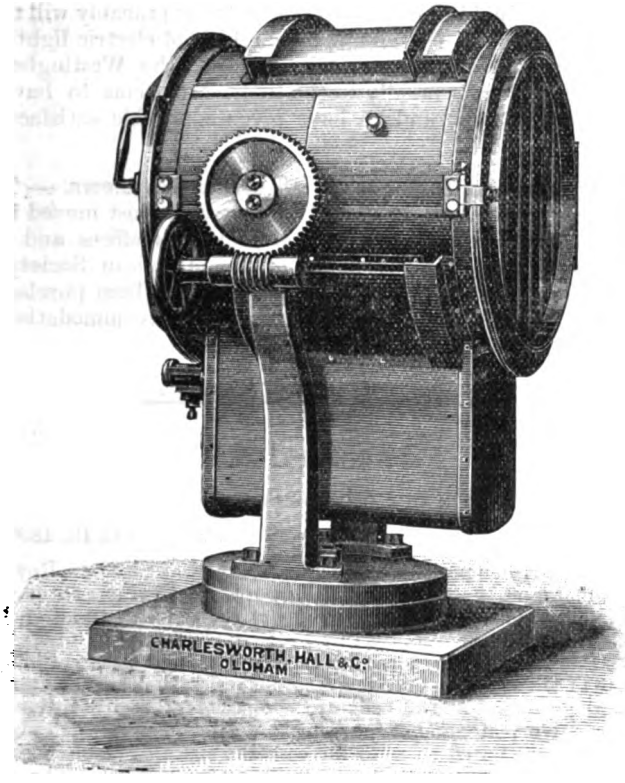

FIG. 1.—Charlesworth Projector.

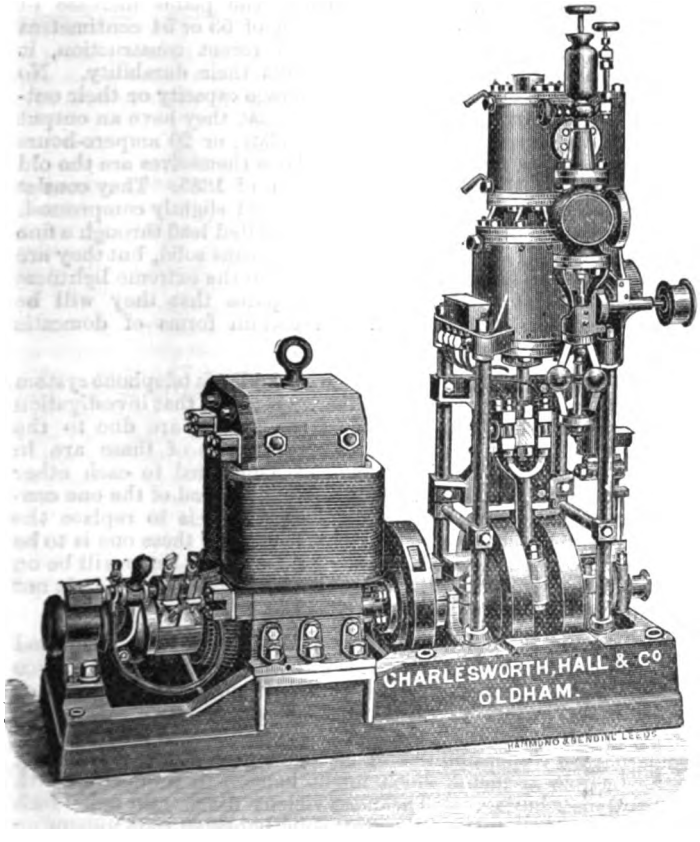

FIG. 2.—Charlesworth combined Engine and Dynamo, for working Projector.

is 16in. diameter, rolled out of steel sheet, and tinplated, making a very strong job. The mirror is Chance Brothers' best quality 16in. diameter, 8in. focus, fitted in a strong brass frame, with a bayonet socket attachment to the barrel to facilitate removal for cleaning, &c. A dispersing lens, also by Chance Brothers, having an angle of dispersion of 16deg., is attached by means of a hinged frame to the forward end of the barrel, in order to fantail the light so as to spread it on the banks. The arrangements for ventilation are very complete, both the mirror frame and projector-barrel being so arranged that a constant stream of cold air passes through, so preventing overheating of the mirror and destruction of the silvering. An instrument similar to a camera is provided at one side of the projector, for viewing the arc. The hand lamp is made detachable, and quite independent of the projector itself. The feed of the carbon is obtained by a right and left-hand thread screw in the usual way. A screw is provided for raising and lowering the carbons, and adjustments are arranged for setting the points of the carbons from below, without having to put the hand in the barrel. With carbons 20mm. diameter, and a current of 45 amperes, these projectors will illuminate a distance of about 1,200 yards.

Fig. 2 shows one of a number of very light and compact sets of electric light machinery, also made by Messrs. Charlesworth, Hall, and Co., specially suitable for ship lighting. One of these sets, as here shown, comprises an engine with cylinders 4in. and 5½in. by 4½in. stroke, driving a Hall dynamo direct at 500 revolutions per minute, with an output of 65 volts 50 amperes, the steam pressure being 60lb. per square inch. As will be seen, the engines are of the open frame type, the cylinders being supported on four steel columns, which also carry the crosshead slide. Both cylinders are fitted with piston valves, operated by one eccentric, the high-pressure cylinder exhausting direct into the low-pressure steam chest, so doing away with connecting pipe joints and stuffing boxes for the valve spindle. The pistons are steel castings fixed on one piston rod of Whitworth steel by means of cones and nuts. The piston-rod glands are tightened by screwed caps, so as to prevent galling, through one side being screwed more than the other, as sometimes happens with glands tightened with studs. A play of $\frac{1}{32}$in. is allowed in the gland for any slight bend in the piston-rod. The end of the piston-rod is passed through a cast-steel slipper slide block, and there screwed by two nuts which are pinned in position. This slide block has slips for taking up wear. The connecting rod is of cast aluminium steel. Both the large and small ends are of the usual marine type. The crank-shaft is of Whitworth steel, with circular crank webs and cast-iron balancing discs shrunk on. In order to reduce wear the crank-shaft and all other bearings are made of very large surface, and all parts can be lubricated while running. The dynamo is one of Messrs. Charlesworth, Hall, and Co.'s inverted type. The magnets are of best soft iron, tooled all over. The armature shaft is of Vickers' steel. The resistances are as follows:—Armature ·21 ohms, shunt 20·65 ohms, series ·0318 ohms, and giving an electrical efficiency of 79·6 per cent.

THE GERMAIN DRY CELL.*

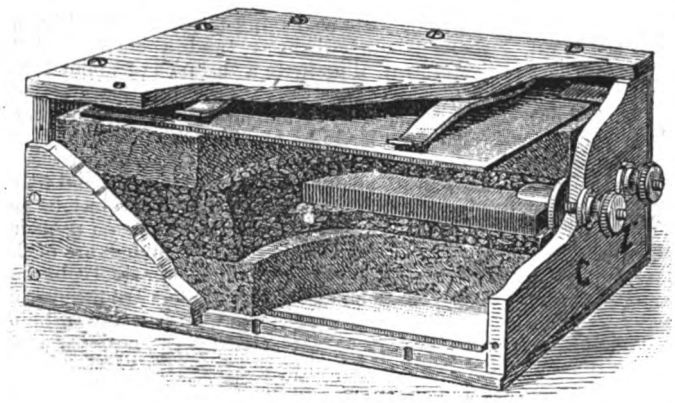
The material made use of by M. Germain in his dry cell consists, as we have previously mentioned, of cellulose prepared from cocoa-nut fibre, which contains, besides pure cellulose, mineral salts, an organic colouring substance, and some fatty substances. The fibre is first of all treated by a process which deprives it of the fatty substances. It is then possible by various methods, which do not alter the physical nature of the fibre nor destroy the cellules, to obtain several kinds of cellulose, possessing greater absorptive and retentive properties than does cellulose in its natural state. These varieties of cellulose are not, moreover, affected by the active agents commonly employed in primary batteries. The particular variety of cellulose employed in dry cells is almost unaffected by ammonium chloride air or the ammonia to which the reaction of the Leclanché battery gives rise. Its apparent density is about ·06 to ·105. Without external pressure it absorbs from 10 to 11 times its own weight of liquid, and when subjected to a pressure of 100 grammes per square centimetre, it still retains 7·6 times its own weight of liquid.

The greater the compression of the paste the greater is the internal resistance of the battery, and with excessive pressures the resistance of the paste may amount to three to four times that of ordinary liquid. Some accumulators, however, furnished with this fibre have been found to have a smaller resistance than if liquid alone was employed. M. Meylan is of opinion that this is due to the fact that the accumulator plate is not a purely metallic electrode, but that it consists partly of oxides of relatively poor conductivity in a state of variable aggregation, and often making bad contact with the lead grid. The pressure of the fibre has the effect of ensuring a better contact; so that while the resistance of the electrolyte

* From *L'Electricien*.

Digitized by Google

increases that of the plate diminishes, the diminution, however, being greater than the increase. In the particular case of the dry Leclanché cell, the effect of pressure is to ensure a uniform consumption of the zincs and to notably diminish the resistance of the mixture of carbon and binoxide of manganese, at the same time effecting more perfect depolarisation—phenomena which were observed some years ago by MM. D'Arsonval and Abdank-Abaknowicz. Moreover, the property which cellulose possesses of absorbing gases prevents the formation of a layer of gas on the surface of the electrodes. On the other hand, the evaporation of the liquid, if permitted, would give rise to non-conducting efflorescences, and at the end of a short time the battery would have such a high resistance that it would be no longer capable of being used.



The annexed figure represents an ammonium chloride dry cell, as arranged by M. Germain. The case is of oak, well boiled in paraffin, and rendered water-tight by a coating of tar. A zinc plate, which is well amalgamated on one side and varnished on the other, rests at the bottom of the box. The fibre is laid on the zinc plate layer by layer, having previously been saturated when warm with a solution of ammonium chloride (density 1·1) in the ratio of 1 by weight of cellulose to 3·5 or 4 of liquid. When this first layer is completed the carbon is placed upon it, surrounded with pieces of carbon and binoxide of manganese. A second layer of fibre is then laid upon the carbon, and upon this a plate of zinc. The wooden lid, to which are fixed several strong varnished steel springs, is then screwed down. The pressure usually employed is about 200 grammes per square centimetre, at which pressure the liquid slightly exudes against the zinc plates. The E.M.F. of the dry cell is uniformly 1·5 volts, the internal resistance varying, of course, with the size of the cells. Thus, a cell (Type B), $12 \times 7 \times 7$ centimetres, has an internal resistance of 1 ohm. The cell (Type G), which is 30 centimetres long, 20 centimetres broad, and 11 centimetres high, has an internal resistance of ·09 ohm, intermediate sizes having corresponding resistances.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 6, 1890.

The Consolidation of Electrical Interests.—Combinations and rumours of combinations seem to be the order of the day just at present. The latest combination is one between the Westinghouse and the Pullman interests. It is understood that Mr. Pullman acquires a large interest in the Westinghouse companies; and that by a united effort the Westinghouse electric railway business will be pushed vigorously to the front. Another rumour is in the air that a fourth great electric railway company will soon take the field, backed by no less a corporation than the Standard Oil Company. With an active management and the millions of the Standard Company behind it, there is a chance for pretty lively skirmishing in the railway business during the next few years. The details of this last organisation have not been made public. Besides this, the Julien Company is a party to an important storage battery traction combination, which will announce itself very soon.

The Electrical Situation in New York.—The electrical situation in New York is unaltered. The Board of Electrical Control, which has rendered itself obnoxious to electricians at large, has temporarily subsided, and there is no likelihood of immediate trouble from it. Meanwhile the ingenuity of divers inventors is being taxed to devise various subway systems suitable for use in the streets of New York.

New Systems of Lighting.—The Edison Company is making vigorous efforts to push its system of arc lighting for incandescent circuits. The Company possesses a lamp that is said to be thoroughly valuable for this purpose, and that probably will take its place as one of the prominent methods of electric lighting. Meanwhile the alternating arc system of the Westinghouse Company is coming rapidly to the front. It seems to have a great many friends, and to have given admirable satisfaction wherever it is used.

The American Institute of Electrical Engineers. — The American Institute of Electrical Engineers has just moved into new quarters on Thirty First-street. It has offices and will hold its meetings in the house of the American Society of Mechanical Engineers, which has but recently been purchased and fitted up with every convenience for the accommodation of a scientific society.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *June* 18, 1890.

Last week some public experiments took place with a new Reynier accumulator at the works of M. Durafort. M. Reynier, not having been able to prevent buckling in any of the ordinary types of lead plates hitherto employed, set to work to render buckling innocuous. With this view he now separates the electrodes by means of porous sheets of silica, which only increase the resistance of the cells to a very slight degree. The cells are composed of two positive and one negative plate, and of four sheets of silica, the two end sheets of silica being fluted so as to increase the space available for the electrolyte, the quantity of which, however, is small. The containing vessel is of sheet iron, lined with india-rubber, and it is therefore light and elastic. A battery of 20 elements is about 50 centimetres long; during discharge the plates increase in volume, the cells expanding till a length of 53 or 54 centimetres is reached. As the cells shown were of recent construction, it is impossible to say anything as regards their durability. No official test has been made as to their storage capacity or their output for weight, but the inventor asserts that they have an output of 30 ampere-hours per kilogramme of plate, or 20 ampere-hours per kilogramme of total weight. The plates themselves are the old lead plates of M.M. Reynier and Simmen, of 1885. They consist of very fine lead wires woven into a net, and slightly compressed. These lead wires are obtained by passing melted lead through a fine colander. The plates, so made, are by no means solid, but they are supported by the sheets of silica. Owing to the extreme lightness of this accumulator, M. Reynier anticipates that they will be largely used for traction work and certain forms of domestic lighting.

A Bill relating to the reorganisation of the Paris telephone system has just been laid before the Chamber. It states that investigation has shown that the grave defects of the system are due to the existence of twelve separate exchanges; most of these are in cramped situations, and all of them are connected to each other by an insufficient number of trunk wires. Instead of the one central exchange originally proposed the plan now is to replace the twelve existing exchanges by four new ones. Of these one is to be in the centre of Paris in the Rue Gutenberg, and three will be on the outskirts. Until this reorganisation has been effected it is not proposed to take on any new subscribers.

Recently, at the Conseil Municipal, M. Charles Laurant invited that body to come to an agreement with the Préfecture de Police with a view to enforcing the use of smoke-consuming furnaces or coke furnaces at the central lighting stations of Paris. The same worthy counsellor also demanded that rules should be drawn up regulating the responsibilities of electric supply companies, owing to the terrible accidents which might happen in connection with electrical distribution. "The most violent flash," said he, "such as is capable of destroying the most solid lightning rods measuring 2½ centimetres in diameter, has been estimated by scientists to be the result of an electric force of about 9,000 amperes. Now, to supply one single Edison lamp during one hour an equal quantity of electricity is necessary." The Conseil Municipal was much agitated at this startling statement, and immediately voted urgency.

CORRESPONDENCE.

BICYCLES FOR TELEGRAPH MESSENGERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to your remark in *The Electrician* of May 30th, that bicycles would not be suitable for roughly-paved streets, it may be worth pointing out that with the so-called "pneumatic tyre," invented by Mr. Dunlop, of this city, riding on a pavement of "square setts" is much easier than on an ordinary macadamised road. The road is always more or less uneven, while the pavement is usually evenly laid; and the jar in passing over the separate stones is completely annulled by the elasticity of the tyre, a thick rubber tube inflated with compressed air. I weigh over 16 stone, and when on these tyres consider the tramway pavement a luxury.—Yours, &c.,

J. BROWN.

Belfast, June 16, 1890.

LEGAL INTELLIGENCE.

In Re Automatic Electric Railway Signal Company.

A petition to wind up this Company compulsorily, it being already in voluntary liquidation, came before Mr. Justice Stirling on Saturday last, the petitioners being Messrs. Blakey, Emmott, and Co. (Limited), the principal creditors, represented by Mr. Yate Lee. Their case was that the liquidator appointed under the voluntary liquidation was the secretary of the Company; and there was a probability of the patents belonging to the Company, which formed the main portion of the assets, and might turn out to be very valuable, being sold for a small sum to a syndicate, and thus the creditors would be left out in the cold. It appeared that the patents in question had been purchased by the Company for £75,000 in vendors' shares, and it was suggested that they would be sold for a very small sum to the Directors or their nominees.

Mr. BARDSWELL, on behalf of the Company, opposed the petition, and was supported by the other creditors, who were of opinion that it would be disastrous if a compulsory order were made. The liquidator denied there was any intention to sell the assets improperly. He was perfectly willing to give the petitioner all the advantages he would have if there were a compulsory order, and would undertake that no sale should be made without notice to the petitioner, or without the sanction of the Court.

In the result his Lordship said he saw no reason to remove the present liquidator, but he would make a supervision order, which he did not think would substantially increase the expense.

The Self-Winding Clock Company.

An application in the liquidation of the Self-winding and Synchronising Clock Company, which was ordered to be wound up on June 29th last, came before Mr. Justice Stirling on Saturday last, the object of which was to settle on the list of contributories three gentlemen named Crossfield, Bennett, and Myers. The liquidator found their names on the register, and accordingly put them on the list; but, on settling the list in chambers, they disputed their liability, and the summons was then adjourned into court. Mr. Whinney appeared for the official liquidator, and Mr. Onslow for Crossfield and Bennett; Mr. Myers did not appear.

Mr. WHINNEY said that the defence in each case was that they had been induced to take shares by misrepresentation, but no summons had been taken out or motion made to remove their names either before or after the liquidation.

His LORDSHIP, after hearing the evidence, ordered the three names to be retained on the list.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Bishop's Stortford Local Board invite tenders for lighting the public streets of the district for one year, from August 16th next. Tenders are to be in by July 17th.

THE TELPHERAGE COMPANY.—Notice is given that the creditors of this Company are required by July 12th next to send in particulars of their claims against the Company to the liquidator, Mr. W. R. Pryor, 50, Old Broad-street, and, if required, are to come in and prove their claims.

INSTITUTE OF MEDICAL ELECTRICITY.—This Institute is removing from No. 24A, Regent-street, Waterloo-place, S.W., to No. 35, Fitzroy-square, W. The new premises will be occupied in about a fortnight.

MESSRS. WILKINS AND CO.—Messrs. Wilkins and Co., of the Submarine Telegraph and Wire Rope Works, Wapping, E., inform us that they have recently completed extensive improvements in their works, and rely upon their long-established reputation for excellence in material and workmanship to secure them extended orders for their manufactures.

MESSRS. J. E. H. ANDREWS AND CO. (LIMITED).—We have received from this firm a price list of the "Stockport" Gas Engine, in which illustrations are given of the new design double-acting engine without slide valve, and of the new vertical type engine. Stock sizes of these engines are from ¾ horse to 20 horse-power.

MESSRS. A. L. THOMAS AND SONS.—We have received from this firm illustrated particulars of their patent bush for fixing the ordinary bored pulleys and coupling to shafting, &c. By using this bush, pulleys can be fixed on shafting or spindles in less time than in the ordinary way; and the difficulty and expense of fixing ordinary pulleys upon shafting, which is often of full diameter in places and has to be reduced by filing or turning, is overcome by this device. The bush can be used on either rolled or turned shafting, and the pulley does not require to be taken off the shafting.

THE AMERICAN BELL TELEPHONE COMPANY.—The number of instruments in use by this Company on May 20th last reached the large total of 460,503.

THE THOMSON-HOUSTON COMPANY OF AMERICA.—The following statement of gross sales and profits of this Company, for the three months to April 30th last, is issued, and will be perused with interest:—

	1890.	1889.	Increase.
Gross sales	$2,133,099	$1,139,833	$993,266
Profits	$650,724	$299,613	$351,111
Motors ordered	1,106	247	859
Generators ordered	112	16	96

THE UNITED EDISON MANUFACTURING COMPANY OF NEW YORK.—We have received a well-illustrated pamphlet from this Company, giving detailed particulars of the Edison electric light system. The frontispiece to the pamphlet shows the very extensive machine works of the Company. Full descriptions are given of the Edison dynamo, ampere meter, pressure indicator, incandescent lamp, vases, standard sockets, double-pole switches, &c.; and following these descriptions is a copy of a circular containing a number of questions sent out by the Company to purchasers of their plant. The answers, in a large number of cases, are also given, and very great satisfaction is expressed by the various local companies whose central station plants have been put down by the Edison Company. The pamphlet also shows copies of testimonials from large users of the Edison system, and concludes with a standard specification for Edison electrical plants.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

May 24, 1890.

8,116. G. BINSWANGER and G. FRANKS. London. Improved handles for electrical switches.

8,144. E. J. PRESTON (on behalf of the firm of Stone and Company and E. W. de Rusett). London. Improvements in apparatus for lighting and ventilating ships' cabins and other places.

8,174. J. RICHARD and F. RICHARD. London. Electrical apparatus for transmitting to a distance the rotation of a signalling or indicating axis.

May 27, 1890.

8,233. W. A. A. DOWDEN. London. The extraction of gold from its ores, consisting of a form of copper plate amalgamated with mercury, the action of which, in retaining the gold upon it, is aided by the passing of a current of electricity.

8,241. C. L. JEFFERS. London. Improvements in electric lamp hangers.

8,242. W. R. LAKE. London. Improvements in and relating to electric-welding or metal-working apparatus (H. Lemp, United States).

8,253. J. KRIEGER, F. STITZEL, C. WEINEDEL, M. SCHWARTZ, A. REUTLINGER and J. H. EGELHOFF. London. Improvements in systems of circuits for electric semaphores.

8,254. R. HADDAN. London. Improvements in the manufacture of plates for electric accumulators.

May 26, 1890.

8,272. S. B. WILKINS. Edinburgh. Improvements in the construction of electrical fire or burglar alarms.

8,286. J. T. TODMAN. London. An improvement in electrical cut-outs.

May 29, 1890.

8,306. H. H. LAKE. London. Improvements relating to electric relays (E. F. Law, Russia).

8,325. J. M. A. PONCIA. London. Improved method of preventing injuries to submarine cables, which he designates "Chafe indicative alarm wires" (H. Kingsford, Peru).

May 30, 1890.

8,362. E. DUMMER. London. Improvements in electric locomotives.

Digitized by Google

8,392. W. P. Thompson. Liverpool. Improvements in tubes or conduits for electric cables (Jacob Frères et Cie., France).

8,393. B. M. Drake, J. M. Gorham, and P. J. Pringle. London. Improvements in switches for electrical circuits.

May 31, 1890.

8,427. A. Apps. London. Improvements in electric arc lighting.

8,471. E. H. Morgan. London. An improvement in electrically driven locomotives.

8,474. C. A. McEvoy. London. Improvements in electrical switches.

8,477. S. F. Beevor. London. Improvements in electric switches or apparatus for making and breaking electric circuits.

June 2, 1890.

8,495. P. H. Williams. Egham, Surrey. Reducing speed of or stopping railway trains by magneto electricity, automatically or otherwise, and utilising the electricity by storage in accumulators for lighting or other electrical purposes.

8,528. B. J. B. Mills. London. Improvements in devices for transmitting power, and especially for transmitting power from electric motors used for the propulsion of vehicles (E. H. Johnson, United States).

8,534. N. de Bernardos and Lloyd and Lloyd. London. Improvements in secondary batteries or electrical accumulators.

June 3, 1890.

8,559. W. Rixom. Barnes. An improved electric wall plug or socket for connecting electric wires.

8,567. H. B. Cobb. London. Improvements in or relating to conductors and conduits.

8,578. J. Y. Johnson. London. Improvements in electric accumulators or secondary batteries, and in the manufacture and production of plates or elements therefor (C. Hering, France).

8,599. F. Anderson. London. Improvements in apparatus for the generation, distribution and commutation of electric currents.

June 4, 1890.

8,651. T. Smith. London. Improvements in casing for electrical conductors, cables, or the like.

June 5, 1890.

8,677. J. Garrow and C. Christie. Glasgow. An automatic machine for testing the strength of the wrist and muscles of the arms.

8,703. W. P. Thompson. Liverpool. Improvements in electric welding (C. L. Coffin, United States).

8,716. E. Edwards. London. A new or improved process for obtaining, by electrical decomposition, metallic zinc from solution of sulphite of zinc.

8,730. W. H. Miner. London. Electric soldering irons.

June 6, 1890.

8.754. T. A. Garrett and W. Lucas. London. Improved apparatus for protecting electric conductors from damage by lightning.

8,758. R. Collachi and N. Rolland. London. Improvements in electric generators.

8.777. H. H. Lake. London. Improvements in and relating to electric call-bells (P. Hathaway, United States).

8.778. H. Groswith. London. Electric motors.

June 7, 1890.

8,880. W. P. Thompson. Liverpool. Improvements in or relating to electric accumulators (Isaac Pearl, Spain).

8,853. A. Piat. London. Improved combined brake and circuit making and breaking device for use with electric motors.

8,854. L. A. W. Desruelles and K. F. O. Chauvin. London. Improvements in and relating to apparatus for measuring electrical energy.

June 9, 1890.

8,872. F. Suter. London. Improvements in electrical lamp holders.

8,892. A. Muirhead and C. R. A. Wright. London. A new or improved method of insulating electrical conductors and conduits for the same.

June 10, 1890.

8,933. G. H. Felt. Glasgow. Improvements in the method of and apparatus for depositing metals by electro deposition.

8,964. R. Kennedy. Kilmarnock. Improvements in electro-motors.

8,976. J. D. Case and C. W. Evans. London. Improvements in and relating to electrically operated musical instruments, and more especially of the piano type.

June 11, 1890.

9,028. S. H. Brooks. London. Improvements in arrangements and mechanism for stopping machinery when a thread or sliver, or other material operated upon, breaks or becomes absent, or when a given length has passed or a bobbin or spool is full, by means of electricity applicable to machines for preparing and spinning fibrous materials, and to other machinery.

9,030. C. H. Freedman. London. Primary battery for open-circuit work.

9,061. S. Z. de Ferranti and A. Wright. London. Improvements in electric meters.

June 12, 1890.

9,089. L. Henrie, H. Pückert, and Geo. Toennies. London. An unconsumable candle, an improvement on arc-lamp electric lighting.

9,124. Jean Jaques A. Aubert. London. An electric counter.

9,125. J. E. Kingsbury. London. Improvements in telephonic apparatus. (The Western Electric Company, United States.)

9,130. C. R. Heap and S. Sharp. London. Improvements in the means of and apparatus for the regulation of electric currents or their effects.

June 13, 1890.

9,138. H. A Bigland and J. Burns, Newcastle-on-Tyne. Apparatus for working electric light arc lamps and other electric appliances by means of twist rod or rods.

9,163. F. M. Newton and T. Hawkins, London. An improved automatic electrical switch or cut-out for use in connection with dynamos and accumulators to be charged thereby.

9,164. F. M. Newton and T. Hawkins, London. Improvements in electric switch boxes and switches.

9,165. F. M. Newton and T. Hawkins, London. Improvements in electrical switches.

9,166. F. M. Newton, London. Improvement in electric switches.

9197. P. P. Alexander. London. Improvements in electrical fuses.

9212. J. G. Statter and S. L. Brunton. London. A method of and apparatus for utilising fixed electro motors for elevating, hauling, and other like applications.

9227. H. Leak. London. Improvements in street and other lamps, also partly applicable to incandescent electric lamps.

9246. J. Ronczewski. London. An electro-magnetic separator.

9257. S. Wohle. London. Process for effecting electrolytic deposit of aluminium.

COMPANIES' MEETINGS.

Poole and White (Limited).

The statutory meeting of Poole and White (Limited) was held on the 13th inst., at the offices, 58, Bread-street, Cheapside.

Mr. JOHN TRYON, who presided, explained that the business had been in existence for about five months. It was originally contemplated to have for the present restricted the operations of the Company to the sale of goods manufactured for them by other firms. It was speedily found, however, that this arrangement would not be satisfactory, and they were now manufacturing entirely for themselves. The Directors believed that the property acquired by the Company, including the interest of Mr. White in his valuable inventions in connection with the manufacture of switches and other electrical apparatus, would result in good profits to the shareholders. It had been suggested by many people that the Company was nothing more nor less than a branch of Woodhouse and Rawson United (Limited). Such an idea was absolutely without foundation, the two Companies having no connection with each other beyond the ordinary business relations which existed between them and other electrical firms. Some pretext for this idea might perhaps have arised from the fact that Woodhouse and Rawson United (Limited) wished to manufacture for the Company; but such an arrangement would have been wholly impracticable.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

ALLEN, EVERITT, AND SONS (LIMITED).—Objects: To take over as a going concern the business now carried on by William Edward Everitt at the Kingston Metal Works and the Stephenson Works, Birmingham, and in London and elsewhere, under the name of Allen, Everitt, and Sons, manufacturers of and dealers in copper and brass tubes, sheets, and wire, and yellow and other metal and brass founders, adopting therefor an agreement with the said William Edward Everitt, the particulars of which are not specified in the Articles of Association. Capital, £300,000, in £10 shares, of which 10,000 are Preference shares.

THE COLUMN PRINTING TELEGRAPH COMPANY (LIMITED).—Registered by Rollit and Sons, 12, Mark-lane, E.C., with a capital of £100,000, in £1 shares. Object: To acquire certain patents and rights in relation to printing telegraph machines, in accordance with an agreement, made June 5th, between Alexander M. Aitken, jun., of the one part and John Gennings, on behalf of the Company, of the other part. There shall not be less than three nor more than seven Directors. The first are the Right Hon. Earl of Wharncliffe (chairman), Viscount Lymington, M.P.; the Hon. A. Brand, W. H. Hurlburt, and Roderick Pryor. Qualification, £200. Remuneration: Chairman, £500; other Directors, £200 each.

DICK, KERR, AND CO. (LIMITED).—Registered with a capital of £160,000 in £5 shares. Object: To carry on business as manufacturers of rolling stock railway and tramway appliances, engines and machinery of every description, and as iron and steel founders and electricians, in accordance with an agreement, made May 31, between Frederick Manuelle and John Kerr of the first part, George Fleat of the second part, and G. W. Carr, on behalf of the Company, of the third part.

KENT PATENT ARC LAMP COMPANY (LIMITED).—Objects: To acquire rights in respect of inventions in connection with electric or other lighting or illuminating purposes, and in particular to adopt an agreement dated June, 1890, made with Mr. John Kent. Capital, £10,000 in £5 shares. Registered, June 13th, by Leslie, Antill, and Arnold, solicitors, 1, Gresham-buildings, London

TUBULAR FRAME WAGON COMPANY (LIMITED).—This Company was registered on the 6th inst., with a capital of £200,000, in £1 shares, 400 being Founders' shares, to manufacture railway and tramway wagons, cars and carriages, and to acquire inventions relating thereto, and generally to carry on business as civil, mechanical or electrical engineers. Solicitors: Messrs. Johnson, Budd and Johnson, 24, Austinfriars, E.C.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended June 13, 1890, amounted to £4,571.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons due July 1st next on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking house of Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

GREAT NORTHERN TELEGRAPH COMPANY.—A half-yearly interim dividend, at the rate of 5 per cent. per annum, will be paid on July 1st next by Messrs. C. J. Hambro and Son.

THE HELIOS COMPANY.—The Helios Electric Light and Telegraph Construction Company, of Ehrenfeld, Cologne, which owns the Ganz Alternating-Current Patents for Germany, has increased its capital from 1,100,000 to 2,200,000 marks (£110,000).

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—At a Board meeting of this Company, held on Monday last, the Directors decided to recommend, subject to audit, a final dividend of 6s. 6d. per share, free of income-tax, in respect of the year ended 31st December, 1889, making, with the interim dividend of 3s. 6d. already paid, a total of 5 per cent. for the year. Subject to the approval of the meeting of shareholders, to be held on the 4th proximo, the dividend will be paid on and after that date. The transfer books of the Company will be closed from the 27th June to the 4th July, both days inclusive.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this Company for the half-month ended June 15th show an increase of £124 as compared with the corresponding period of last year.

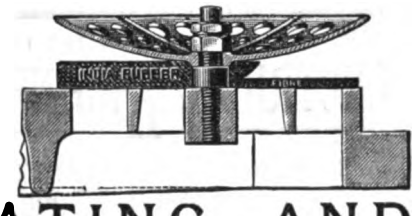
WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended June 13, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,543.

WESTINGHOUSE ELECTRIC COMPANY.—The stock of this Company is to be increased $3,000,000, or from $5,000,000 to $8,000,000. Mr. George H. Pullman is to take the entire issue at par, or $50 a share.

WOODHOUSE AND RAWSON UNITED (LIMITED).—We are asked to deny the statement made in a financial contemporary that the Chairman of this Company has resigned, in which statement we are informed there is no truth.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 20th Sept. 1886.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 632.—Vol. XXV. FRIDAY, JUNE 27, 1890. Price Fourpence.

NOTES.

The startling announcement made by the Postmaster-General, that the Government have decided not to purchase the undertakings of the Telephone Companies, is of too great importance to be dealt with in a short editorial note; but one thing may be briefly said of the decision at once, namely, that it is as disappointing as it was unexpected. Although one of the two telephone patents expires in December of this year, and the remaining patent in the following May, the patentee's license to work them runs for another twenty years. There will, therefore, presently be created the unprecedented novelty of a virtual monopoly being worked without any legal patent, or else that of an unrestricted competition being carried on against a virtually legalised monopoly. One other alternative, indeed, is open to the Post Office Telegraphs, that of becoming sole competitor with its own licensee, which perhaps would be the greatest novelty of all. From whatever point of view the future is now regarded, it is beset with complications of most serious moment for all the parties concerned.

The immediate cause of the unfortunate fire which occurred last Saturday at the house of Mr. R. D. Sassoon is, as usual in such cases, somewhat obscure. The casings and wooden-backed switches were, so we hear, run in new plaster; and investigation now shows that for some time past a gradual breaking down of the insulation had been going on, resulting in the establishment of a general leak. The section of the battery which is discharging on to the house lamps is not, so we understand, always disconnected from the charging main; so that an earth, on a house circuit, coupled with another on the charging main, might give rise to unpleasant consequences. According to one informant, "electric sparks were seen all over the house" at the time of the occurrence, a phenomenon which, if it is accurately described, would point to the presence of a high potential current in the house circuit. On the other hand, the Cadogan Company state that careful tests of their circuits showed nothing wrong, and that the charging of the remaining batteries was renewed without difficulty soon after the fire occurred. Whoever is to blame we trust we shall have no more of these unfortunate mishaps, a few of which would completely neutralise the confidence in the electric light which the good work of the past few years has in so large a measure restored.

At the meeting of the Physical Society on Friday last, the results of an important research on the measurement of electro-magnetic radiation were experimentally shown by Mr. Vernon Boys. It will be remembered that Mr. Gregory some time since succeeded in measuring the expansion of a fine wire caused by the heating effect of the electrical oscillations set up within it; and, with the view of confirming this result, Mr. Boys has employed two distinct methods, the application of which has needed great ingenuity and manipulative skill. One of these methods, depending on the mechanical forces exerted between two adjacent wires in which oscillations were induced, appeared at first to succeed, owing to an extraneous effect; but after this had been carefully eliminated, no action could be detected, although the adjustments were delicate enough to indicate a force of less than a one hundred-millionth part of a grain. This failure may be partially attributed to the mutual influence of the oscillations in the two closely adjacent wires, since, owing to the difference of phase so caused, the force between them would be lessened. There is, however, good reason to believe that with the increased delicacy obtainable by employing parabolic reflectors, measurements of this force may yet be successfully made; and, if so, many problems in electrical theory may then be solved. Hitherto measurements in connection with electric oscillations have only been of the roughest kind, but, as soon as a satisfactory method of measurement is found, we may reasonably look for the experimental solution of many questions about which the mathematicians at present dispute with huge armies of symbols; and we may expect that the simplification of our ideas brought about by the solution of these problems will be of service in practice as well as theory.

The second method used by Mr. Boys depended on the use of a modification of a very delicate thermometer invented by Joule, and after some trouble this was made to succeed. The result found was in perfect accordance with that of Mr. Gregory, and the heating effect caused by the electric oscillations is thus conclusively established. The discussion which followed the reading of the Paper was of considerable interest; and Sir W. Thomson, while agreeing in the main with Mr. Boys' views, pointed out that with electric oscillations, in which the duration of the forces is so short as to be comparable with the time taken to propagate them, it was impossible to distinguish the electro-static from the electro-dynamic forces. The law of action between rapidly moving charged bodies is, in fact, not understood, and is one of those

Digitized by Google

problems which may be solved by methods similar to those used by Mr. Boys.

We publish this week a method, due to Mr. Brew, for determining the self-induction of a coil by means of a Cardew voltmeter. The method is of some interest, since it requires very simple apparatus; it is, however, of limited application, for an alternating potential of known frequency must be available, and the coil to be tested must be capable of standing the currents and potentials for which the Cardew voltmeter is used. The variation of the resistance of the voltmeter with the magnitude of the current will not be any serious disadvantage when the impedance of the coil is as large or larger than that of the instrument, except in the few cases when very accurate measurements are required.

M. Gouy, who has already devoted considerable time to the study of the law of the quadrant electrometer, has recently given his attention to the use of that instrument for ballistic purposes. From the account of his work, which we publish in another column, it will be seen that an encouraging amount of success has been obtained with an electrometer whose needle was suspended with a fine wire, and whose oscillations were undamped except by air friction. A good ballistic electrometer would be a very valuable instrument for many purposes, some of which are so obvious that they have probably occurred to others as well as M. Gouy. The difficulty of making a satisfactory instrument has, however, hitherto been too great for experimenters to surmount; and M. Gouy may therefore be congratulated on the skill he has shown. Practical electricians look upon electrometers with rather too much awe, as instruments whose delicacy renders them only fit for laboratory use. Until quite recently, little time has been devoted to them since Sir W. Thomson first introduced the quadrant type, and, in consequence, but few improvements have been made. If they had been as much studied as galvanometers, we might now be in possession of an instrument which could, like the D'Arsonval type of galvanometers, claim, at the cost of some degree of sensitiveness, the much more desirable qualities of ease and certainty of working. The need of instruments for alternate-current measurements has redirected Sir W. Thomson's attention to the improvement of electrometers; and the valuable results of his efforts are well known. We are, however, of opinion that there is a much more brilliant future for electrometers than their use at present gives any indication of, and the communication of M. Gouy clearly shows a new series of useful applications.

We have received from the Weymersch Battery Syndicate the copy of a lengthy report on some tests of this battery recently undertaken by Messrs. Alabaster, Gatehouse, and Co. We published some two years ago a similar report upon the same battery by the same authorities; and the *raison d'être* for this second document is not very apparent, since the main differences between the conditions of 1888 and those of the present date consist in the diminished size of the cells, the substitution of porous plates for pots, and some slight variation in the strength of the exciting and depolarising solutions.

These tests, however, at the same time that they prove the depolarising solution compounded by M. Weymersch to be a good one, show what a very limited field in reality lies open to a primary battery intended for what may in this connection be termed heavy work. Even if we suppose that the depolarising solution is to be sold at the lowest possible price, and take into consideration only the cost of materials, 1,000 watt hours supplied by a Weymersch battery still cost 1s. 6d., as against the 6d. to 10d. charged by an electrical supply company. It will be urged, no doubt, that it is just where there are no electrical supply companies, and where large installations are not warranted, that there is room for a good primary battery. For dentists' motors, miners' lamps, and amateurs, primary batteries have their uses; but for ordinary house-lighting, unless the inventors of these secret solutions will also undertake to supply competent domestics, a Bunsen cell, however modified, is not likely to meet with any great demand. The everyday manipulations which a battery such as the one in question requires are quite beyond the resources of the small houses for which its capabilities alone fit it. To keep only seven 16 candle-power lamps burning during a winter's evening it would be necessary every day to handle, taking out exhausted and pouring in fresh liquid, 42 gallons of dilute sulphuric acid, and every fourth day 22 gallons of depolarising solution. Unless, therefore, the extended use of primary batteries results in the evolution of a new form of domestic servant, this consideration alone seems to us to preclude the idea of any extensive demand for primary batteries for house-lighting even on the smallest scale.

Honours to M. Gramme.—The Société d'Encouragement has awarded the Ampère medal to M. Gramme.

Zürich.—An electric tramway on the overhead wire system, 2·5 kilometres long, is to be built at Zürich. Water power is available.

Steno-telegraphy.—M. Cassagnes' steno-telegraphic instrument has been placed in the Museum of the French Postal Telegraph department.

Cambridge.—The Town Council have appointed Dr. J. A. Fleming to advise them on the best way of carrying out the electric lighting of the town.

Cardiff.—At the last meeting of the Lighting and Electrical Committee of the Corporation it was decided to recommend the Corporation to apply for an electric lighting Provisional Order.

Troyes.—On Saturday last the central lighting station of the Compagnie Nationale d'Électricité was inaugurated. According to the *Bulletin Internationale de l'Electricité*, M. Ferranti was present at the ceremony.

Electric Lighting Acts Amendment (Scotland) Bill.—This Bill passed through Committee in the House of Commons on Thursday last week, and was read a second time in the House of Lords on Wednesday last.

Leeds.—The deputation from the Electric Lighting Committee of the Leeds Corporation has returned from London; and a report will shortly be presented to the full committee, and afterwards to the Council.

The Telephone in Spanish Colonies.—By a recent royal decree the Minister of the Colonies has been authorised to make concessions for telephonic services in the islands of Cuba, Porto Rico, and the Philippine Isles.

Valencia.—A Central Station has been erected at Valencia by Mr. Ramon Cases, head of an electric light company at Madrid. Örlikon dynamos are used, and the lamps, &c., are supplied by the Allgemeine Elektricitäts-Gesellschaft.

Digitized by Google

Edinburgh Exhibition.—On Saturday last the Lord Mayor of London visited the Exhibition, and after examining several of the Sections he opened the telpher line, and said he hoped the invention would be very much taken advantage of by the public.

The Tudor Accumulator.—According to the *Electrotechnisches Echo*, the Allgemeine Elektricitäts Gesellschaft and Siemens and Halske intend to erect a factory for the manufacture of Tudor accumulators in connection with Müller and Einbeck, the present makers.

Electrical Trades' Section River Excursion.—Some difficulties have arisen in arranging this excursion, owing to the regulations for the Henley regatta. Nearly 60 places have been applied for. Applicants will be informed as soon as definite arrangements are made.

Brighton.—The Town Clerk has received a communication from the Local Government Board, sanctioning the borrowing of the necessary money for carrying out the electric light works at Brighton. The sums required are £32,500 for the electric lighting, and £4,500 for the store yard.

Weston-super-Mare, Clevedon, and Portishead Tramway Bill.—This Bill, the object of which is to obtain extension of time for the construction of works, and to authorise the use of electricity on the tramway system, was passed last week by a Committee of the House of Commons.

Barmen.—According to the *Gas World*, the electric light in this town has produced favourable returns, while at the same time the gas consumption has so greatly increased that a new gasholder, of a capacity of 530,000 cubic feet, is urgently required, and is being got ready for the autumn.

The Thomson Alternate-Current Motor at the Royal Society Soiree.—It may be worth mentioning that the Thomson alternate-current motor, which attracted so much attention at the Royal Society *soirée* last week, was actuated by a current generated by the Ferranti alternator at Deptford.

Electrical Execution.—It has been decided by the Court of Appeals of the State of New York that Kemmler is properly in the custody of the warden of Auburn Gaol. The sentence of execution by electricity passed upon him will therefore be shortly carried out unless further legal complications arise.

The Peral Submarine Torpedo Boat.—The Spanish Government has, on the proposal of the Minister of Marine, conferred a title of nobility upon Lieutenant Peral, of submarine boat fame, and presented him with £20,000 for services to his country, and as a testimony of his countrymen's gratitude.

The Fritsche Dynamo.—In some tests of this machine recently undertaken by Herr Uppenborn, he states that he ran an 8-pole machine, giving an average of 112 volts 177 amperes at 180 to 182 revolutions for three hours, and found the rise in temperature of the armature to be 14·7°C., and in the field magnets 19·0°C.

House of Lords.—A Select Committee, presided over by Lord Belper, on Thursday last threw out the Bill recently passed by the House of Commons, authorising the Whitehaven Gas Company to extend the limits of their supply, to erect works, and supply electricity, and to raise £25,000 additional capital for this purpose.

The Ward Electrical Omnibus.—On the return of the Lord Mayor from Edinburgh he was met at Euston by the electrical omnibus owned by the Ward Electrical Car Company. The omnibus, which was driven by Mr. Radcliffe Ward, the managing director, conveyed his lordship and the Town Clerk to the Mansion House.

Insuring Employes.—The Detroit Electric Light and Power Company has adopted a plan of insuring its employés, every one of whom carries a $5,000 policy, the premiums upon which are paid by the Company so long as he is in its employ. The arrangement insures the employé's family in case of accidents, and protects the Company from damage suits.

Press Rates in Hungary.—The Hungarian Minister of Communications, M. Baross, proposes to reduce the telegraph tariff for Press messages from 2 kreuzers to 1 kreuzer per word. For the present, however, this reduction will only be granted to newspapers which receive 60,000 words per annum from Hungary, and which will deposit a guarantee for so doing.

Telephonic Communication between Belgium and Germany. The Telegraph Departments of these two countries have again taken up the question of establishing telephonic communication between Brussels, Verviers, Aix-la-Chapelle, and Cologne. In Belgium the wire has already been taken to Welkenraedt on the German frontier, and it only remains for the gap between Welkenraedt and Cologne to be bridged over in order to complete the line right through.

Telegraphs in the Dutch West Indies.—The Dutch Government, says *Industries*, has impounded the caution money deposited by the Pedro Segundo Telegraph Cable Company, of New York, which has failed to carry out its contract for the laying of a cable connecting Paramaribo, the capital of Surinam, with Cuba and Florida, *viâ* Curaçoa. The same contract, or a similar one, has now been undertaken by the Compagnie Française des Télégraphes Sousmarins, in Paris, against a Government subsidy of £2,000 per annum.

A Destructive Flash.—During a recent storm at Playford, Suffolk, a poplar tree, about 300 yards away from the church, was struck by lightning, and the bark was completely stripped from top to bottom, the southern half of the body being riven into matchwood. One piece, 5½lb. in weight, was picked up 126 yards away from the tree, and the *debris* covered about two acres of land. The discharge left the tree at the foot, following the direction of a fence for about 15 or 20 feet, threw up a sod about a foot square, and went to earth.

Electric Lighting in Victoria.—Electric lighting, it would seem, is a very profitable business in Victoria. At the first half-yearly meeting of the A. C. Alcock Electric Light and Motive Power Company, the Chairman stated that but for the fact that the Directors had decided to allow 10 per cent. instead of 5 per cent. for plant depreciation, the Company would have been enabled to show a profit at the rate of 20 per cent. per annum for the six months. What the rate of profit was, however, when 10 per cent. was allowed for depreciation does not appear.

The Breakage of Submarine Cables.—The suit of the Western Union Company against the Inman Steamship Line was decided on Tuesday last in the United States Court. The decision was against the Western Union Company. The suit was brought for breakage of telegraph cables by the propeller of an Inman Line steamship becoming entangled in them. The steamship company filed a counterclaim for 2,000 dollars, damages done to the ship's propeller. The Court allowed this counterclaim. Presumably the cable was attached to a buoy the position of which was not properly indicated.

The Reverchon Watchman's Signal.—An ingenious electric signal for a factory watchman, worked on a single circuit, is described in a recent number of *Cosmos*. The arrangement consists of a single wire, with its return going in series to each post. At every post there is a commutator, the movement of which by the man on his rounds throws in a fine wire resistance. At the office there is a revolving drum, on which an ink needle attached to a galvanometer traces a mark. As each successive resistance is switched in, the deflection varies and leaves a trace of the time of the watchman's signal.

The Electrical Purification of Sugar Juices.—Some sugar works in Havana have recently been provided with purifying plant in which osmosis and electrolysis simultaneously are at work. The sugar juices are poured into the middle compartment of a series of troughs, which are divided into three by two porous partitions. The outside compartments contain water, in which are placed blocks of carbon connected to the negative pole of a dynamo. The positive pole of the machine is connected to carbon plates in the middle compartment. The sugar juices are purified from the salts they contain, which are taken up by the water. The addition of the current seems to assist the osmotic transfer across the porous partitions.

The Protection of Linemen.—An arrangement for the prevention of accidents by the electric current has been adopted at the works of the Morgan Engineering Company, of Alliance, Ohio. A board is fixed on the wall facing the dynamo in the engine-room. On this board are six hooks for the checks of the six men who are employed in looking after the circuits. When a man is called on duty he removes his check from the hook

Digitized by Google

and takes it with him. The engineer sees by a glance at the board that one check is absent, and that, therefore, one man is engaged about the lines around the shop, and the dynamo is not started until the check is replaced on the hook.

Metropolitan Provisional Orders.—The Board of Trade have granted Provisional Orders to the House-to-House Electric Light Supply Company for a portion of the parish of St. Mary, Lambeth, the parish of Islington, and the district of the Wandsworth Board of Works, comprising the parishes of Wandsworth, Clapham, and Putney. A Provisional Order has also been granted to the St. James's and Pall-mall Electric Light Company for the parish of St. James's, Westminster, and to the London Electrical Supply Corporation for an area comprising the whole of the parish of St. George-the-Martyr, Southwark, together with a portion of the parish of Camberwell.

The Lightning Conductor Question in Germany.—The *Electrotechnische Zeitschrift* of June 13th contains the report of a long Paper by Dr. Neesen on the interminable question, "Should lightning conductors be in metallic connection with the gas and water pipes or no?" This is a subject which seems to have an irresistible attraction for the German mind; and for the last two years or so the technical papers have never been free from it. In connection with the Paper it is mentioned that the *Electrotechnische Verein* would be glad to receive accounts of lightning strokes bearing on the subject. They should be addressed to Herrn Prof. v. Bezold, Kgl. Meteor. Institut. Berlin, W., Schinkelplatz 6.

Folkestone.—At the last meeting of the Town Council, the Electric Light Committee reported that they had had an interview with the representative of Messrs. Crompton and Co. upon the question of their contract to light the town by electricity. The Committee stated that it was very unsatisfactory, and it was decided to bind them to their original contract. Councillor Thompson, in moving that the report be received, said as they were unable to enter into any arrangement to have the light produced within any reasonable time they came to the determination that the only course was to hold them to the original contract—that the light be supplied by the 1st July. The report was received without comment.

The Kensington Vestry.—At the last meeting of this Vestry the Works Committee reported that they had considered as to the great amount of extra work devolving upon the surveyor in connection with the supervision of works being carried out by the several electric lighting companies within the parish, and had ascertained from him that the companies were prepared to pay him a reasonable sum to compensate him for the additional work which he is called to carry out. The Committee therefore recommended that the surveyor be authorised to accept such compensation from the electric lighting companies, subject to his reporting to the Committee from time to time the amount which he has received from them.

Greenwich Observatory.—We extract the following notes about Greenwich Observatory from the report of the Astronomer Royal to the Board of Visitors:—"The continuous registration of meteorological phenomena has been maintained as usual, and all the instruments are in good order. The Thomson electrometer, which had been out of order since the autumn of 1888, was finally adjusted by Mr. White, of Glasgow, and brought into use again in October, 1889, the amplitude of motion of the spot of light being increased more than two-fold. The automatic drop of the Deal time-ball failed on 21 days owing to interruption of the telegraph connections, and on one day high wind prevented the raising of the ball. There have been frequent failures in the return signal, the arrangements for which are not in a satisfactory state.

The Cost of Transmitting Power.—The following comparisons of cost of transmission of power by various methods appeared in the *Revue Universelle des Mines*:—(1) Comparative cost of 10 horse-power transmitted 1,093 yards: By cables, 1·77 per effective horse-power hour; by electricity, 2·21; by hydraulics, 2·90; by compressed air, 2·98. (2) Comparative cost of 50-horse power transmitted 1,093 yards: By cables, 1·35 per effective horse-power hour; by hydraulics, 1·87; by electricity, 2·07; by compressed air, 2·29. (3) Comparative cost of 10 effective horse-power transmitted 5·465 yards: By electricity, 2·64 per effective horse-power hour; by compressed air, 4·66; by cables, 4·69; by hydraulics, 5·29. (4) Comparative cost of 50 horse-power transmitted 5,465 yards: By electricity, 2·37 per effective horse-power hour; by cables, 2·65; by compressed air, 2·99; by hydraulics, 3·02. Steam was the prime mover used in each of the above instances.

The Underground Telephone Lines at Hamburg.—The first underground telephone lines at Hamburg were laid down at the end of last year. The cables are formed of 28 strands, arranged in seven groups of four 1mm. wires. This is lapped with three coverings of cotton, and to overcome induction there is a tinfoil coating connected to a 1mm. diam. copper wire leading to earth, there being one of these earth wires to each group. The cable wires are then coated with prepared tape, over which is a lead sheath. This is covered with a layer of asphalted tape. For the protection of the cable it is covered with 19 tinned iron wires of trapezoidal section 4·7mm. by 4·3mm. by 1·7mm. The diameter of the finished cable is 3·2cm., and the weight per metre 4 kilos. These cables are laid in cast-iron troughs. The covers of these troughs are generally 60cm. below the level of the street. In all 79 cables, having a total length of 30,000m., have been laid.

Jerritt's Military Field Sounder.—This apparatus, which has been devised by Mr. Jerritt, of Plymouth, consists of a small instrument so arranged as to be capable of being used as a transmitter and receiver. By an ingenious arrangement, the lever of the sounder is employed both for sending and receiving messages, thus doing away with the ordinary apparatus for transmitting telegraph work, the current being put on and off by means of a small switch fixed to the base of the instrument. A telephonic arrangement can be adjusted for receiving purposes if required. The instrument, battery, sounding-box, and telescopic stand fold up and form a compact knapsack, and can be comfortably carried as such by any operator. The centre of the stand, it may be mentioned, can be used if necessary as a drum for winding a quantity of wire. The apparatus should prove of use for military purposes, or working parties while erecting telegraph lines for communicating messages to the nearest transmitting station.

The Gilbert Club.—A joint meeting of the Essex Field Club and the Gilbert Club will be held at Colchester on Saturday, July 5th, with the object of affording to members of these Clubs, and any ladies and gentlemen interested in the history of science, and the parts filled by Englishmen in its inception and progress, an opportunity of visiting the birth-place, death-place, and last resting-place of William Gilbert. The party will visit Gilbert's house (anciently known as "Tymperleys" or "Tympornellis"), by kind permission of the owner, and Holy Trinity Church, where is Gilbert's monument. The chair at luncheon will be taken by Lord Rayleigh; and in the evening the Mayor (Mr. Asher Prior) will receive the Societies at the Town Hall at 7-30 p.m. During the evening Prof. Silvanus Thompson will give a lecture on "The Early Magnetic Experiments of Gilbert of Colchester." Anyone wishing for further particulars should apply to Mr. William Cole, Buckhurst Hill, Essex, Hon. Sec. Essex Field Club.

The Edinburgh Meeting of the Institution of Electrical Engineers.—The following circular has been sent round by the Secretary, Mr. F. H. Webb, in connection with the Edinburgh meeting of the Institution:—

Dear Sir,—I beg to inform you that, in compliance with a request of a deputation from the Executive Council of the above Exhibition, an extraordinary general meeting of the Institution will be held at Edinburgh on July 15th, 16th, and 17th next. Among the Papers to be read, in the lecture hall of the Exhibition, will be the following: "On some of the Chief Features of the Exhibition, and mainly of the Electrical Section," by Prof. Robert M. Walmsley, D.Sc., F.C.S., Associate. "The Working Efficiency of Secondary Cells," by Prof. W. E. Ayrton, F.R.S., Vice-President, C. G. Lamb, B.Sc., E. W. Smith, and M. W. Woods, Associates. The Executive Council of the Exhibition have kindly arranged for members excursions to the Forth bridge, and in electric launches up the Union canal. The Great Northern Railway Company will grant to members return tickets, available for eight days, at a single fare and a quarter. I am also in negotiation with the London and North-Western Railway Company for a reduction of fares. The hotel accommodation in Edinburgh is very ample, and the tariffs are about the same as in London. As the final programme depends to a great extent on the numbers who will be present at the meeting, it will be necessary, if it is your intention to attend, that you should advise me on or before the 30th inst., when any further details shall be communicated to you as early as possible.

Iron-Filing Curves.—In our issue of March 21st we described a method, due to M. Korobow, of fixing iron-filing curves by means of melted paraffin. M. Decharme, in *La Lumière Electrique* of June 19, urges as an objection against this method that, like most others, it only fixes the curves when the iron filings are no longer under the influence of the magnetising force, so that a *dead* figure (*spectre mort*), and not a *live* figure (*spectre vif*), is reproduced. The method employed by M. Decharme to obtain a photographic reproduction of the *live* curves, which, as he states, differ considerably for strong magnetic forces from those obtained after the magnet is removed, is as follows:—A sheet of ferro-prussiate paper is stretched evenly over a thin glass plate. A magnet is then placed either under or on the top of the glass, and the paper is sprinkled with filings, and smartly tapped, as usual. After the curves have been formed the whole arrangement is immediately exposed to the light, and a photographic reproduction is thus obtained of the *live* curves.

The Marvin Electric Drill.—The Marvin electric percussion drill, says the *Electrical World*, consists of an iron bar, to which a drill is connected, reciprocating axially between two solenoids intermittently energised by pulsations of current delivered to the two coils in alternation over separate circuits, from a special dynamo. The two solenoids are mounted in a boiler tube casing, and the whole apparatus is mounted upon an adjustable support. As the coils are alternately supplied with pulsations of current over separate circuits from a special dynamo, no commutating devices or sliding contacts are required either upon the drill or in its vicinity. The moving parts are simply an iron rod travelling axially, and a ratchet arrangement that serves to turn the drill slightly at each stroke. The whole machine is designed to endure the roughest kind of abuse in mines and quarries. The machines now ready are capable of drilling holes from 1ft. to 8ft. deep and from 1in. to 2in. in diameter. They will cut about 8ft. per hour in granite, and require about 5 horse-power. The drill travels in synchronism with the dynamo, and by feeding the machine up to the rock the stroke may be made as short as is desired for starting a hole, while the number of strokes per minute remains the same. A peculiar property of the machine is that when the machine is withdrawn out of striking range of the rock the plunger immediately loses its stroke. It takes up a position about midway between the coils, and its motion becomes a mere quivering. There is no pounding against buffers, as the rod is perfectly cushioned by the magnetic action of the coils. At full stroke the drill has an excursion of about 4in., and strikes 650 blows per minute. It is of about the same weight and bulk as an air drill of the same capacity.

The Transfer of Provisional Orders.—In answer to a question by Mr. O. V. Morgan last week, Sir M. Hicks-Beach said that he was not aware that Local Authorities had any power to transfer gas or water undertakings acquired by Provisional Order or Act of Parliament without statutory authority; but provisions had been inserted in the Electric Lighting Orders, granted this Session, authorising Local Authorities to transfer their powers and liabilities to any Company or person with the consent of and upon terms to be approved by the Board of Trade. He was advised that such provisions were not *ultra vires*.—On Wednesday evening last Mr. Morgan asked the President of the Board of Trade whether the effect of the provisions which the Board had inserted in Electric Lighting Orders now before Parliament, authorising Local Authorities to transfer their undertakings, would be practically to confer upon the Board of Trade powers to perform functions heretofore exercised by Parliament, and also deprive the public of the means that they now had of resisting any such transfer by appearing before a Parliamentary Committee where evidence was taken upon oath; and whether the Board would have the power to administer an oath if the functions of Parliament were so vested in that department? Sir M. Hicks-Beach said that Section 11 of the Electric Lighting Act, 1882, provides that "no local authority, company, or person shall by any contract or assignment transfer to any other company or person or divest themselves of any legal powers given to them, or any legal liabilities imposed on them by this Act, or by any licence, order, or special Act, without the consent of the Board of Trade." The Provisional Orders granted under the Act referred to require that public notice of the proposed transfer shall be given, and the transfer cannot be made without the consent of the Board of Trade, by whom the deed of transfer must be approved, and who will make any inquiries that they may consider necessary in the interests of the public. The Board of Trade would have no power to administer an oath. With regard to the merits of the clause, he wished to point out that the Local Authorities, who are representatives of the rate-payers, ought to be the best judges of their interests in matters affecting the lighting of the town.

Water Power Installations for Electric Lighting.—In connection with the Paper on this subject, recently read before the Institution of Civil Engineers, the following particulars of Lord Armstrong's hydraulic plant at Cragside, supplied by Mr. Bernard Drake, may be of interest:—The first plant consists of a turbine, having a fall of 385ft., the water being conveyed in a 7in. pipe through a distance of 1,200 yards, the speed of the turbine being 1,300 revolutions. The horse-power obtained is 27, which is utilised for driving two dynamos coupled tandem on the same axis. The distance from the house is about a quarter of a mile, and the current is conveyed partly overhead and partly by bare copper conductors laid in wooden troughing, and carried by flat pottery supports. One of the dynamos is compound-wound, and is used for the direct supply of lamps in the building. As switching off of a portion of the lights would cause the remainder to be overworked, unless the turbine were checked instantly, an electrical system has been worked out to control the turbine automatically. This is effected as follows: The main ring contact-switch placed in the house carries a small separate switch, so arranged that before the main circuit is altered a current is passed through one or other of a pair of magnets fixed near the turbine. These magnets give a pull of 30lb., which is used to open or close a cock leading to the main piston, which opens or shuts the blades of the turbine. An electrical system of starting and stopping worked from the house has also been worked out by Messrs. Drake and Gorham. The second dynamo is used for charging accumulators. The second plant is used for the electrical transmission of power. The fall is 29ft., and the horse-power 10. The generator is driven by a belt, and the current is conveyed to the workshops, a distance of 750 yards, by bare overhead conductors. A continuation of this circuit has been made a further distance of 750 yards to the house, by means of which the current can be utilised for electric lighting in case of emergency. The electric motor drives a large circular saw, and a number of other tools. The motor is compound-wound in a special manner, which enables the work to be removed suddenly without any danger. The third plant is used for ploughing and other farm purposes, such as raising weights for ensilage, &c. This turbine gives 30 horse-power, with a fall of 190ft. The water is conveyed a distance of 400 yards through an almost horizontal pipe of 18in. diameter, and afterwards through 300 yards of 10in. pipe. The type of turbine is that of Prof. James Thomson, made by Gilks and Company, in which the water is taken in at the circumference and discharged at the centre, the speed being controlled by the alteration of the angle of the guide blades. Another of these turbines has recently been fitted by Messrs. Drake and Gorham, in connection with the lighting of Alnwick Castle, where the fall is very low and the horse-power over 30.—Another station, similar to that at Keswick, was erected at Okehampton in December, 1888, by Mr. W. Geen, and has been running successfully without any breakdown up to the present time. A Leffel turbine with 15ft. fall is used. The larger portion of the mains are laid under ground in glazed stoneware socket pipes. Early in 1889, Mr. Geen commenced operations at Lynmouth and Lynton, where alternate-current transformers are used. Two Mordey alternators are being run at present, each having an output of 600 16 candle-power. These are driven by a turbine of the Little Giant type, of special construction to suit the fall, which is 95ft., and giving off 200 horse-power. The turbine is horizontal, with the shaft projecting at each end, and the alternators are fixed in line with the turbine shaft with a suitable coupling at each end, so as to use one or both alternators as may be required.

MAGNETISM IN IRON AND OTHER METALS.*—XXI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 169.*)

§ 84. **Effects of Vibration.**—The influence of vibration and mechanical disturbance generally upon magnetic quality has been shortly referred to in § 64; it may be succinctly described by saying that vibration lessens those differences of magnetic condition to which hysteresis gives rise. Thus, if we tap a piece of iron during the application and removal of magnetising force, we find at each stage of the application that tapping increases the susceptibility, and at each stage of the removal it reduces the retentiveness. Whatever be the exact nature of the molecular rearrangement which constitutes magnetisation it is facilitated by vibration, which may be imagined to act by setting the molecules momentarily free, more or less, from the constraint in which they ordinarily lie. An analogy may be drawn to the way in which iron turnings scattered on a table near a magnet are freed to range themselves along the lines of magnetic force when the table is tapped; but it must not be inferred that the constraint of the magnetic molecules has anything of the quality of mechanical friction. What that constraint probably is will be discussed in a later chapter.

In strong fields the influence of vibration is scarcely felt; in weak fields it is often enormous. The effect in a weak field is well shown by the familiar experiment—described by Gilbert nearly three hundred years ago—of magnetising a bar of iron by hammering it while it is exposed to the earth's magnetic force. Let the bar, for instance, be held upright: the vertical component of the terrestrial field is too weak to produce more than the feeblest trace of magnetism so long as there is no mechanical disturbance. When sharply tapped, however, it becomes a fairly strong magnet, and the magnetism taken up in this way will persist after the bar has been withdrawn from the field until it is expelled by further tapping or by the application of a moderately strong magnetic force of the opposite sign. The magnetism acquired by an iron ship in building is another instance in point, and still another is the magnetism which the shock of rupture produces in a specimen of iron or steel broken in a testing machine. Vibration affects all the magnetic metals more or less, but it is in soft annealed iron wire that its influence is most remarkable. Gentle rubbing will give much magnetism to a soft iron wire suspended in the terrestrial field, or will take away much of the large residue which persists after a strong magnetising force has ceased to act. Much care is, in fact, necessary in experiments on the susceptibility or retentiveness of this material to avoid serious errors through accidental disturbance of the specimen. The effects of hysteresis almost entirely vanish in the magnetisation of soft iron wire, if the piece be briskly tapped during application and removal of the magnetising force. The curves of **I** and **H** or **B** and **H** in the two processes become nearly coincident, and the relation of magnetism to magnetising force becomes comparatively determinate. Two experiments may be quoted to show these effects.†

§ 85. **Experiments on the Effects of Vibration in the Magnetisation of Soft Iron Wire.**—The wire was a piece of very soft annealed iron, 0·158cm. in diameter, and 64cms., or 400 diameters long, of the same quality as that tested in the experiments of § 64. The test was made by the ballistic method; the magnetising force was raised by steps, and after each step the wire was vigorously beaten against the table, and the magnetism was then measured by slipping off a movable induction coil. Observations were made in the same way at a series of stages during the removal of the force. Table VII. gives the values of **B** found after tapping, first, during application, and then during removal of the force, when the magnetising force due to the solenoid had the values stated in the first column.

A glance at the figures will show the enormous increase of susceptibility brought about by tapping. A force of 0·96 in the solenoid, with tapping, brings **B** up to 9,540; but another

TABLE VII.—*Magnetisation of Soft Iron Wire with Vibration.*

Magnetising Force due to Solenoid.	B During Application.	B During Removal.
0	240 (initial)	400
0·04	840	1,440
0·15	3,370	—
0·31	5,370 ↓	5,850 ↑
0·62	8,260 ↓	8,500 ↑
0 96	9,540	9,860
1·60	10,740	11,200
2·92	12,040	12,400
5·04	13,140	13,000
7·00	13,460	13,550
16·8	14,750 →	

experiment on the same piece of wire showed that without tapping the value of **B** under the same force was only 550. In Fig. 54 curves are drawn, with a very open scale of **H**, to illustrate the portions of this experiment which deal with feeble magnetic forces. The full line, O P, refers to the application of magnetic force; the dotted line above it refers to the removal of the force, both with tapping, while the line O Q refers to the application of magnetic force without tapping. The magnetic force plotted here is that due to the solenoid alone, but it is important to notice that this is by no means the true total force in the experiment made with vibration. Though the wire is 400 diameters long, it cannot be treated as sensibly endless. The reaction of the ends becomes very important on account of the excessively great susceptibility. The real field is much less than the field due to the solenoid—how much less may be judged from the line O A, which is drawn (in the manner

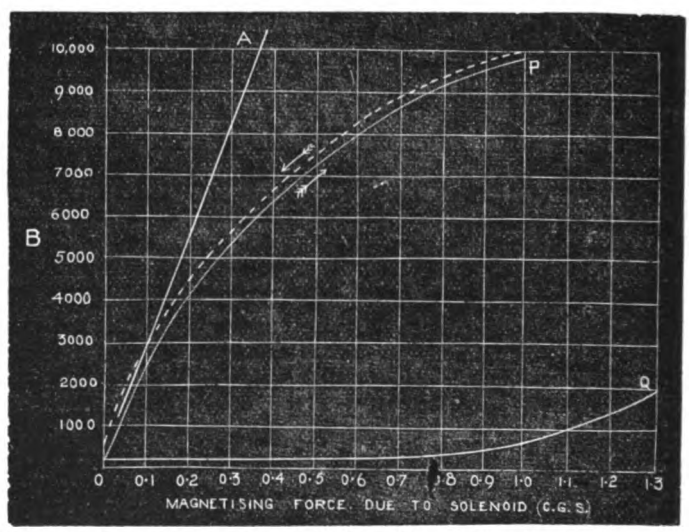

FIG. 54.—Magnetisation of soft Iron Wire; O P, with vibration, O Q, without vibration.

described in § 48) on the supposition that the wire may fairly be treated as an ellipsoid 400 times as long as it is broad. Even neglecting this correction of the magnetic force the ratio of **B** to the (solenoid's) force is not less than 20,000 in the initial part of the curve; and after allowing for the influence of the ends of the specimen the permeability is found to have the enormous value of about 80,000. The permeability is greatest at or near the beginning; the concavity, which is a feature in the early part of curves determined without tapping, has nearly, if not quite, disappeared.

The complete experiment is shown in Fig. 55. The curves shown by full lines were obtained by applying and removing a magnetising force of nearly 17 units without vibration. The curves shown thus — - - - - - refer to the same process performed with vibration. Finally, after magnetising again to the point *a with* vibration, the application of magnetic force was continued *without* vibration, and the results of this are shown by the dotted curve . . . . It is interesting to notice how the hysteresis immediately re-asserts itself when, after tapping, we continue the magnetising process with the specimen at rest.

Digitized by Google

In another experiment, with the same piece of wire, the magnetic force was raised to a certain value, without vibration, while B was determined ballistically; then the wire was smartly tapped, and the change which B underwent through the tapping was measured by slipping off the induction coil; then the coil was replaced, and the force was raised by steps to a higher value; then the wire was again tapped, and so on. The wire had an initial magnetism (B) of 170, which rose to 190 when a force of 0·32 was applied without tapping; then while this force continued to act tapping brought up the value of B at a bound to 6,620. Again, under a force of 1·61 tapping changed B from 7,120 to 11,600, and under a force of 3·4 it changed B from 11,940 to 12,960. Coming down the effects were equally well marked.

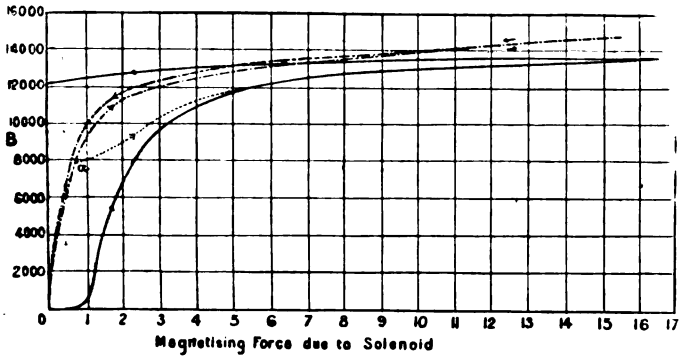

FIG. 55.—Magnetisation of very soft annealed Iron Wire. Without tapping, ———; with tapping, - — - — - — -; continuation, without tapping, after reaching (with tapping) the point *a*, ...

When the force had been reduced from a fairly high value to 0·33, tapping brought B down from 11,260 to 6,880, and finally when the force was 0 the residual value of B, amounting to 6,880, was reduced by tapping to 320. The forces stated here are those due to the solenoid without allowing for the reaction of the specimen itself upon the magnetising field. The complete results of this experiment are shown in Fig. 56, where the full lines show those parts of the process which were performed without tapping; and the changes of magnetic state brought about by tapping, while the external field was kept constant, are shown thus: ——-——-.

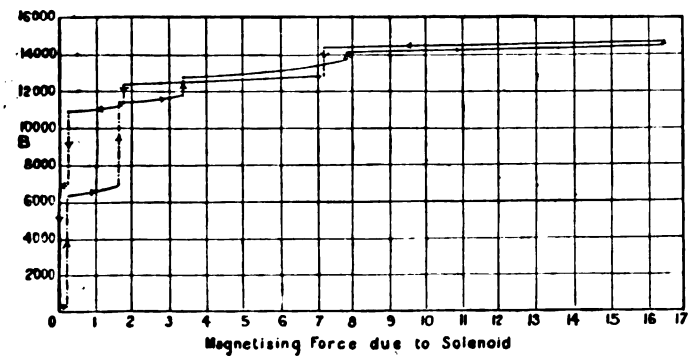

FIG. 56.—Magnetisation of very soft annealed Iron Wire. Effects of tapping shown thus, - — - — - — -.

In experiments of the same kind with hard iron or with steel vibration produces effects of the same general kind; but its influence in destroying hysteresis is far less complete than in soft iron. In a piece of iron wire of the same quality as the last, but not annealed, where a residual magnetism (B) amounting to 7,000 was left after applying a force of 17, the residue fell to 2,500 when the specimen was smartly tapped.

§ 86. Permeability with respect to Small Magnetic Forces.—The instances which have been quoted may suffice to give a general notion of the behaviour of iron and the other magnetic metals when exposed to magnetic fields of moderate strength. It remains to give some account of experiments dealing with the two extremes of weak and strong magnetisation. The effects of weak fields will be taken up first.

A glance at the curves of B and H or of I and H for any of the examples which have been already given will serve to show that the initial permeability—that is to say, the permeability at the beginning of the process of magnetisation—is so small that special means are required to examine its value. The arrangements for measuring this early magnetism, whether they are ballistic or magnetometric, must be much more sensitive than in experiments which deal with later portions of the curve. So small, indeed, is the permeability under very feeble forces, compared with the permeability found later, that without special appliances one might readily fall into the error of supposing it to be initially zero. Experiments made by Baur, Lord Rayleigh, and others are conclusive, however, in showing that this is not the case. They show that the initial permeability has a finite value which is applicable, without sensible change, so long as the magnetising force remains very small. In other words, the magnetisation curve starts with a definite gradient, and its very early portion is nearly straight. Lord Rayleigh has carried his investigation of the action of weak forces further, showing that the permeability has a finite value with respect to any small cyclic change of magnetic force when that is frequently repeated—a value which is sensibly constant when the range of change is varied, provided the range be kept very small, and which is approximately independent of the mean condition as to force and magnetisation, provided the magnetic state does not approach saturation.

Baur's experiments were made ballistically with a ring of soft iron, the cross-section of which had a diameter of a little over two centimetres. Reduced to C.-G.-S. measure, his results for one trial are as follows:—*

H	I	κ
0·0158	0·263	16·5
0·0308	0·547	17·6
0·0708	1·633	23·0
0·1319	3·815	28·9
0·230	9·156	39·8
0·384	22·487	58·6

When these values of susceptibility κ are plotted in relation to H, they are seen to lie on what is practically a straight line. By producing the straight line backwards, the value of κ corresponding to $H = 0$ is found to be 14·5. This is, therefore, the susceptibility with respect to indefinitely feeble forces; the corresponding initial permeability, μ, is 182. Moreover, with respect to forces which are still feeble though not indefinitely small, the susceptibility and permeability may be expressed by the equations

$$\kappa = 14{\cdot}5 + 110\ H\ \dagger$$
$$\mu = 183 + 1382\ H,$$

which apply with much accuracy within the limits of H used in the experiments. With considerably higher force, however, these formulas would not apply. It follows that the relation of magnetisation to magnetic force for feeble forces may be expressed thus:

$$I = 14{\cdot}5\ H + 110\ H^2$$
$$\text{and } B = 183\ H + 1382\ H^2.$$

These particular numerical constants are, of course, to be taken as applying to the specimen of soft iron tested by Baur; but similar parabolic formulas may be constructed with different constants for any specimen of any of the magnetic metals. In other words, the curve of I and H or of B and H is sensibly a parabola in its earliest stages, starting, however, with a finite inclination to the axis of H. For excessively feeble forces it is virtually an inclined straight line, the term involving H^2 being then negligible.

* C. Baur, Inaugural Dissertation, Zurich, 1879. Wied. *Annalen*, XI., 1880, p. 399.

† Baur gives $\kappa = 15 + 100\ H$, but the constants given above seem to the writer to agree better with the numerical results of the tests.

(To be continued.)

IMPROVEMENTS IN CABLE SHIP GEAR.

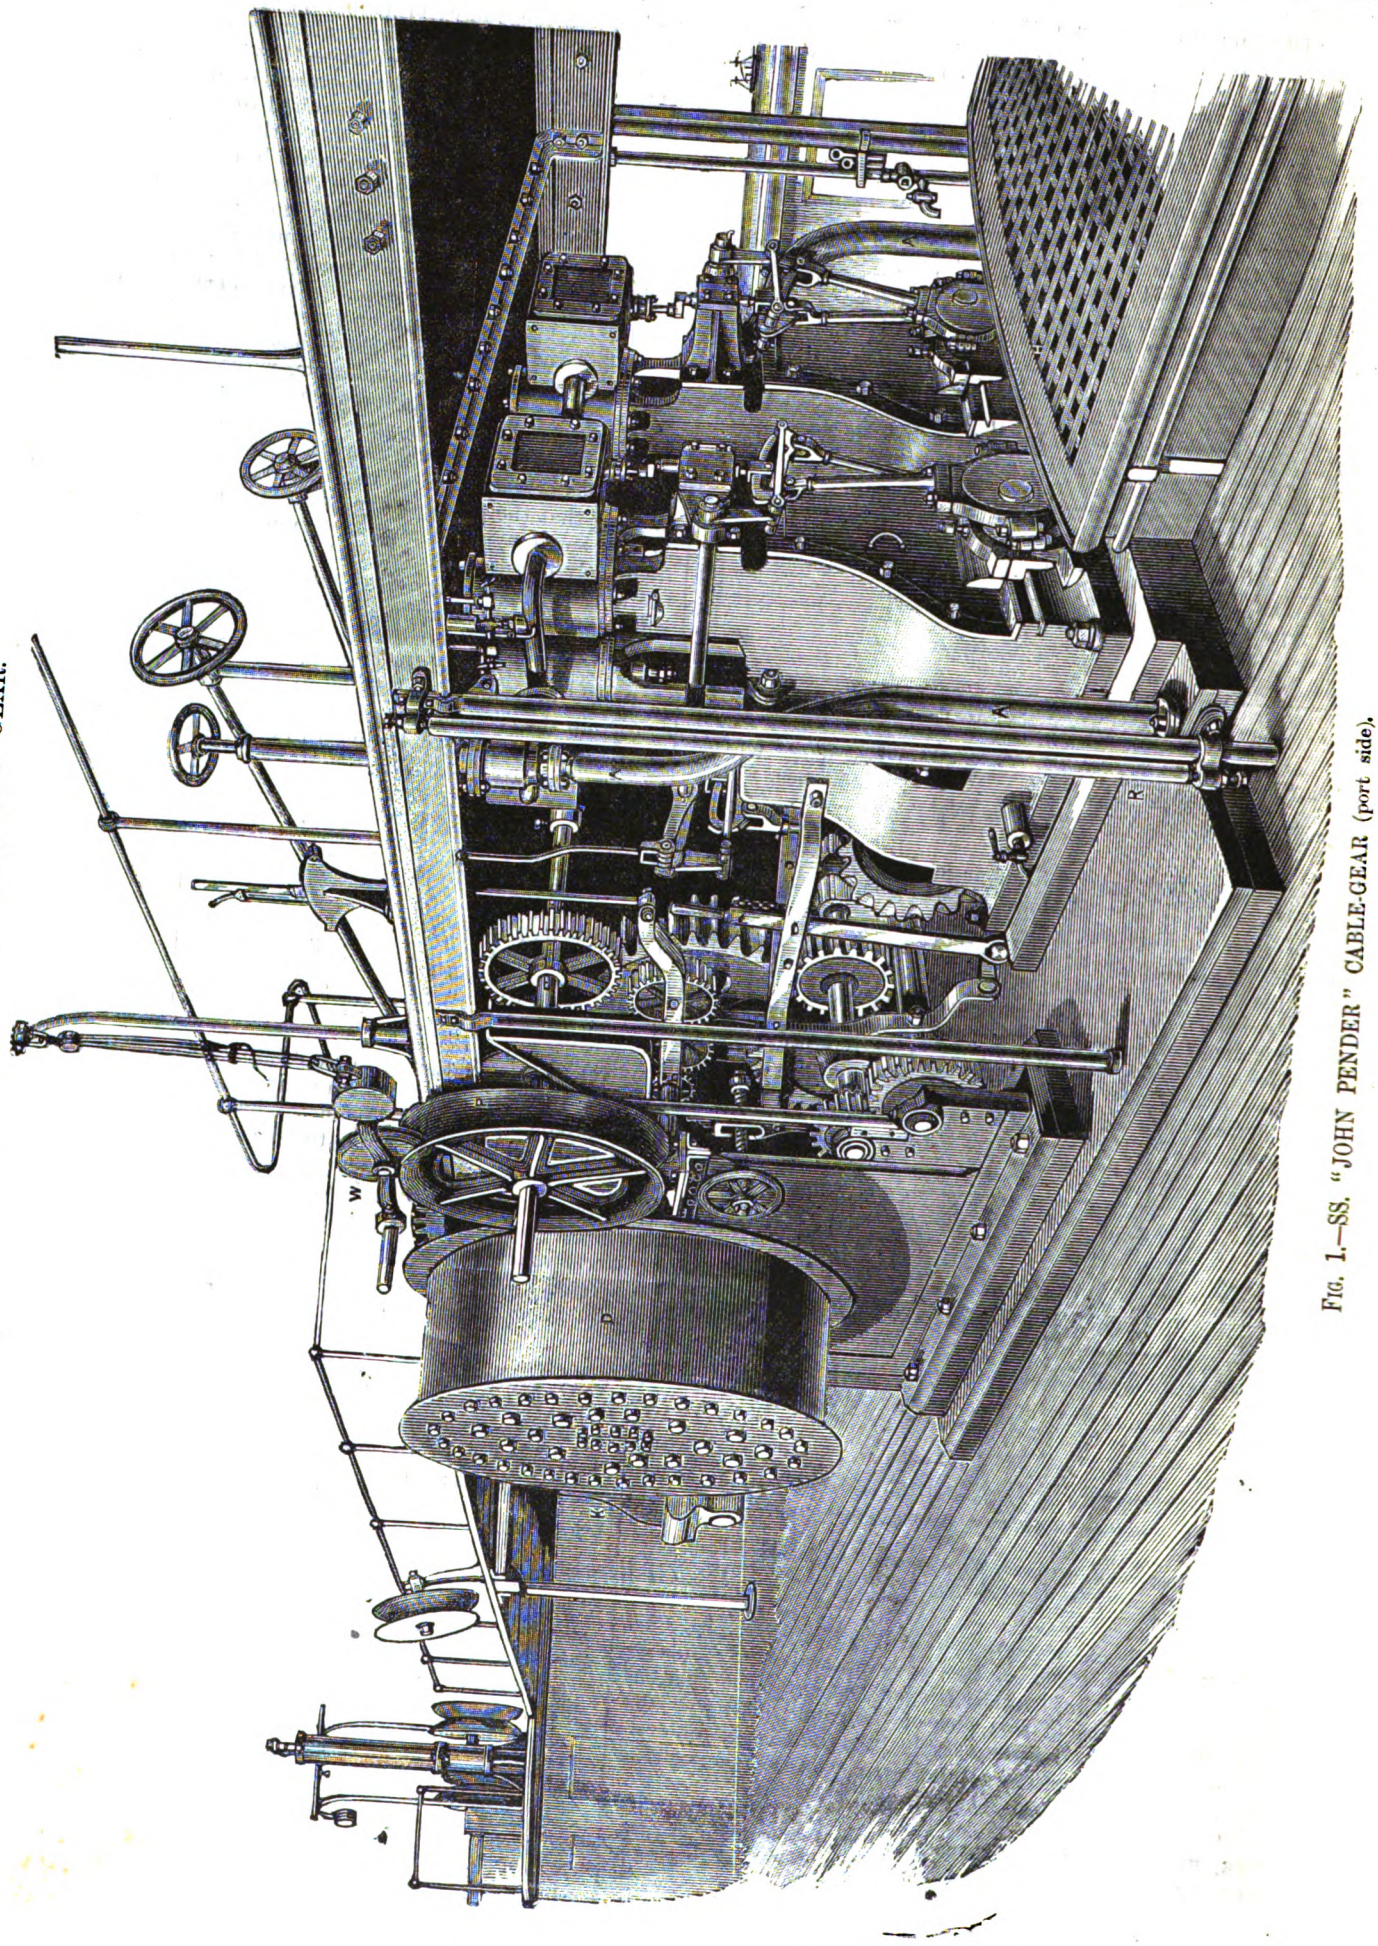

FIG. 1.—SS. "JOHN PENDER" CABLE-GEAR (port side).

Digitized by Google

IMPROVEMENTS IN CABLE SHIP GEAR.

BY H. D. WILKINSON, M.I.E.E.

In the operations connected with submarine cable repairs it has been found of considerable convenience and advantage to have independent control over the picking-up and paying-out gear on board ship when these two operations are carried on simultaneously over the bows.

During repairs, except for very long lengths, it is now the usual practice to pay out over the bows, and when the fault has been removed and the ship has payed out up to the buoyed end to make the final splice, the double operation has to be performed of picking up the rope by which the cable has been moored, and paying out on the repaired end. In ships provided with only one drum forward, it is customary to wind the mooring rope round the drum in the opposite direction to that in which the paying-out cable is wound, so that the one drum performs both operations. This has the disadvantage that as much slack cable is payed out as the length of the mooring rope, which, in deep water, entails the laying of considerably more slack than necessary. To avoid this loss the payed-out end may be made fast; but this is not satisfactory, as the strain on the cable is always great, and may increase rapidly at any moment as picking-up proceeds. In some ships, such as the steamship "Electra" (Eastern Telegraph Company), there are two drums, either of which can be thrown in or out of gear. With this arrangement the drum used in paying-out is coupled to the train of gear driven by the engine until arrival at the buoy, when it is held and controlled by a powerful brake, and thrown out of gear with the engine. The latter then drives the other drum, and hauls in the mooring rope. As the strain increases, the brake is partially released, allowing the drum on the paying-out side to slip and pay out slack to relieve the strain. By this means there is no unnecessary slack payed out. An improvement on this is to provide two independent trains of gear, each with its own drum and driving engine. This has been done in the cable ships "Amber" and "John Pender" of the Eastern Telegraph Company, the engines being horizontal, and the gear designed and fitted by Messrs. Clark, Muirhead and Co., in the case of the steamship "Amber," and the engines vertical, and gear designed and fitted by Messrs. Johnson and Phillips in the steamship "John Pender." It is of the gear recently fitted on board the "John Pender" that this article is descriptive.

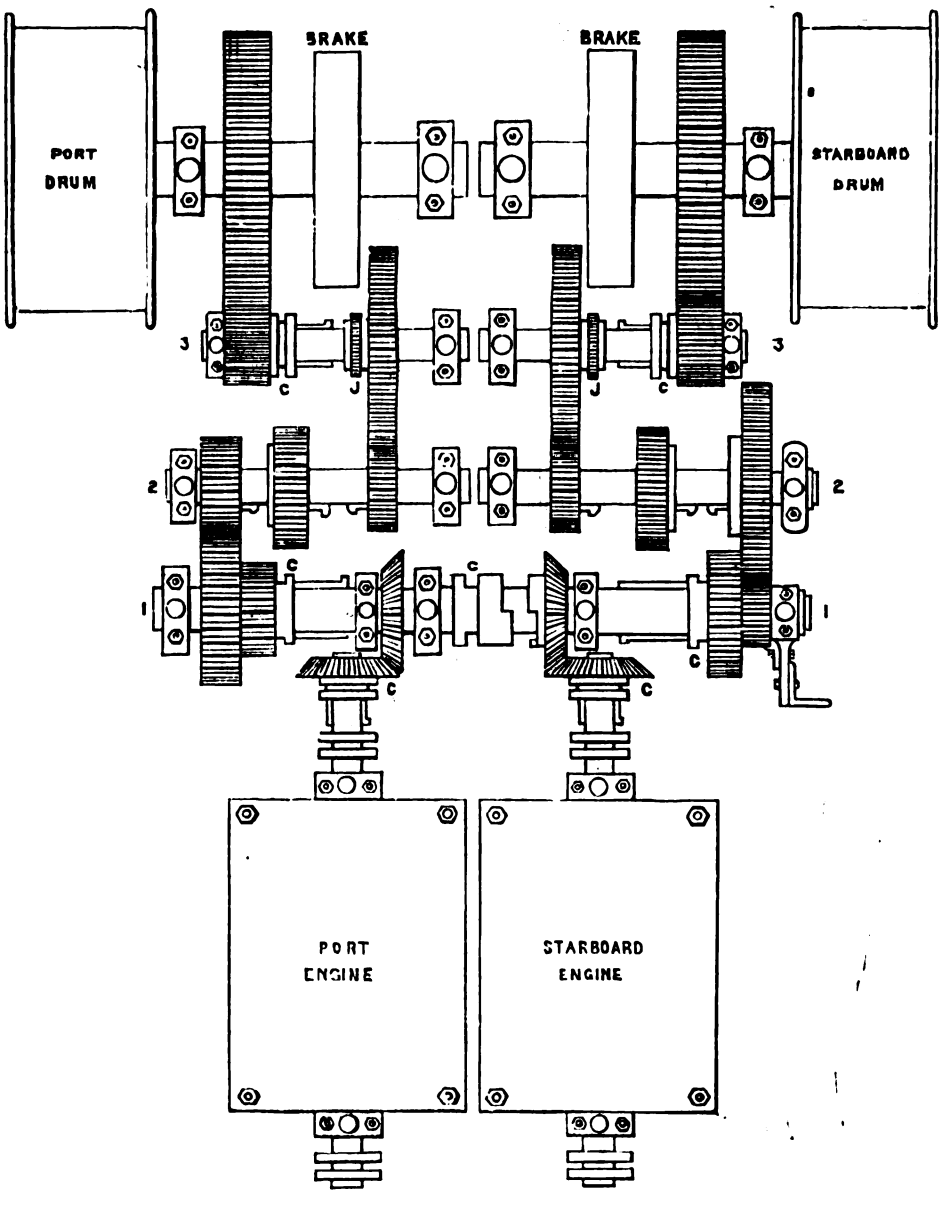

FIG. 2.—Plan of gear

By reference to the perspective view of the gear (Fig. 1) it will be seen that the starting valves of the two engines and their reversing gear are operated from the bridge. From this platform also the brakes on the respective drum shafts are controlled and the jockey pulley thrown in or out of gear. The other changes in the gear are made below the bridge as required. In this view it will be noticed that the hatch opening on the main cable tank is situated close to the gear at H, the ship

Digitized by Google

having two more tanks forward and one more aft. During paying-out, the cable is drawn up from the tank by the jockey wheel and pulley shown at W and P respectively; the traction or hauling power on the cable being regulated by the weight on the lever carrying the jockey wheel. The cable passes through an iron eye in the centre of the hatchway above the tank, round the outside of the vertical roller R, over the jockey pulley P, and three times round the drum D. Thence it is led forward over a guide pulley, under the dynamometer pulley, over a second guide pulley, and over the bow sheaves. When paying out from the aft tank guide pulleys are laid at intervals along the deck to guide it to the jockey and drum. The spindle carrying the jockey pulley carries also a brake wheel, the friction on which is maintained by a lever and weight.

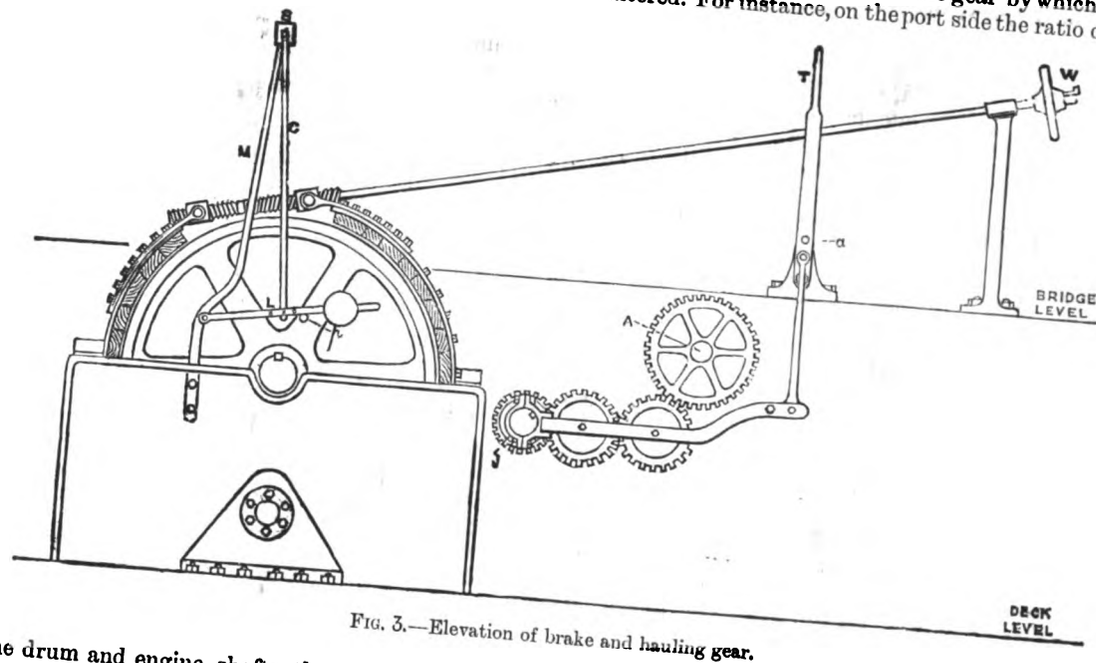

FIG. 3.—Elevation of brake and hauling gear.

Between the drum and engine shafts there are three intermediate shafts for reducing the speed. These run athwartships parallel to the drum shafts, and are numbered 1, 2, and 3 on the plan (Fig. 2) for reference. The engine shafts are fore and aft, and drive by bevel gear on to the first shafts in the train

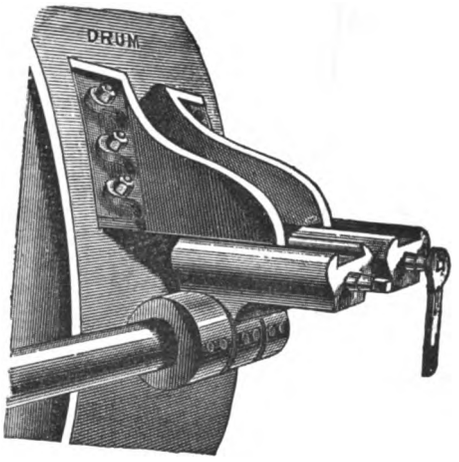

FIG. 4.— Drum knives.

of gear, but can be uncoupled when required by shifting the bevel on the engine shaft. The port and starboard No. 1 shafts can be coupled together by the central coupling C if required; thus both trains of gear can be run by one of the engines, and this can be made to operate either or both drums. For this purpose the cog wheel driving that on the drum shaft can be shifted along a feather on No. 3 shaft, so as to disconnect the corresponding drum from the gear. On No. 3 shaft is keyed a small spur wheel J, operating the jockey pulley spindle. This gear is best seen in Fig. 3, in which the spindle is at A, and has keyed to it a spur wheel, as shown. When the lever T is vertical, this wheel is thrown into gear with the shaft at J. To uncouple the pulley from the gear, the pin at *a* is removed and the lever T let down. This is required when paying-out with the brake on the drum only; the pulley is then free from the train of gear, and revolves by the friction or weight of the cable passing over it. The object of this pulley being to guide the cable to the drum, the shaft on which it is mounted projects by the width of the drum, and the pulley (which slides on a feather) can be made fast by a set screw in any required position.

Between the first and second shafts of the transmission (*see* plan) there is a single and double gear by which the speed may be altered. For instance, on the port side the ratio of the speeds of the drum and engine shafts may be either as 6 : 100, or as 3 : 100, according to which gear is used. The type of brake used is shown in Fig. 3, where W is the hand wheel on the bridge, by which one of the brakes is adjusted. This operates a right

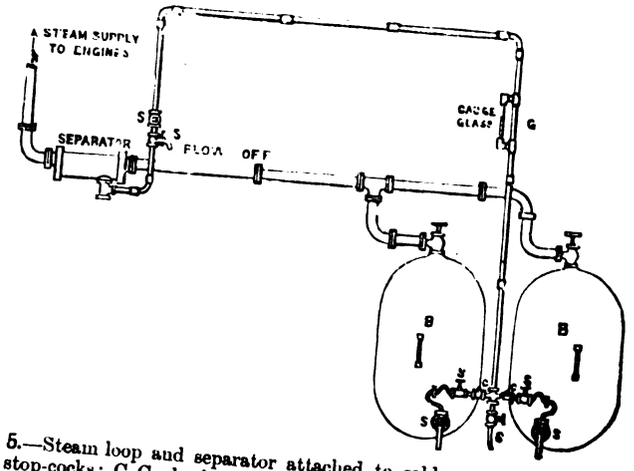

FIG. 5.—Steam loop and separator attached to cable-gear engines. S, S, stop-cocks; C, C, check or non-return valves; B, B, main boilers. (The steam-pipe connections to main engines not shown.)

and left-handed screw, gripping or releasing the brake. In this figure the speed counter gear is shown at S. This is operated by a lever L, fulcrumed on the fixed arm M, which receives an upward movement every revolution by the pin *p* attached to the cog-wheel on this shaft. This movement affects the speed counter through the arm C. The drum has a circumference of 18 feet, and therefore 30 fathoms of cable are payed out for every ten revolutions. For keeping the turns of cable in the centre of the drum the knives shown in Fig. 4 and at K in Fig. 1 are provided. These can be adjusted in position with

Digitized by Google

respect to the drum face so as to prevent banking up against the cheeks of the drum and overlapping.

The engines are by Messrs. Robey and Co., and, as will be seen in the engraving, are double cylinder verticals. The support to the cylinders in each engine is in two castings, bolted together with front and back plates, forming a hollow framework, in which the crank shaft revolves in oil and water. This framework forms internally the guides for the crossheads, and to it are bolted externally the brackets for valve spindle guides and reversing gear, the links and excentrics for the latter being outside. The vertical space occupied by the engines and gear between the main deck and bridge is about 6ft. 6in., the stroke being 15 inches. Sight-feed lubricators are fitted to each engine. The holding-down bolts are secured underneath the deck, which is of iron, by 8-inch baulks of timber and large plate iron washers.

The steam pipes are shown at A A, being connected together underneath the deck, and running into the steam pipe supplying the forward winch and windlass. Immediately below the deck a steam separator is inserted in the steam pipe, from which a 1½in. drain pipe is led upwards, as shown in Fig. 5. This drain pipe is carried along horizontally at the height of the bridge to the engine-room, where it is dropped and connected to the main boilers through check and stop valves, as shown. This

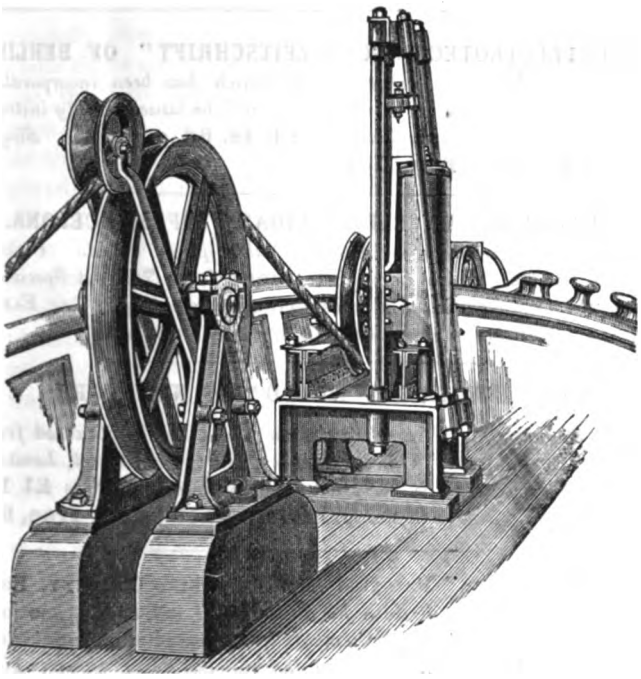

Fig. 6.—Paying-out gear (aft).

returns all water drained from the separator direct to the boilers, the action of the apparatus depending on the increased pressure due to the height of water in the vertical portion of the piping dropped to the boilers. It appears strange at first sight to see a drain pipe from a separator carried upwards instead of downwards, and still more so to see that there is sufficient pressure to return water to the boilers; such is, however, the case, as may be noticed at any time by shutting the stop-cock at the boiler. The accumulated water then rises in the pipe, and may be noticed at the gauge glass G, instantly descending and entering the boiler on re-opening the stop-cock. The system is an American patent worked by the "Steam-Loop and Separator Company," and appears to be of considerable utility in providing dry steam to engines situated at a distance from the boiler. At sea there is the additional advantage of economy in fresh water. The separator is of special construction. Steam passing through it is checked in its course by striking against a set of vertical combs, so arranged that the steam pursues a zigzag course between them. In so doing it delivers its moisture up, which runs down the combs, and through holes into the drain below. The Edison Electric Light Station at Chicago has this system installed with the best results, and it seems not improbable that it may prove of great service to electric light installations, where trouble is experienced from condensation in steam pipes and cylinders.

When cable is paid out aft it is passed up from the tank over a series of guide pulleys on deck, and finally under the dynamometer pulley shown in Fig. 6. In this figure the guide pulley immediately preceding the dynamometer is shown, the cable being maintained in the groove by a small pulley fixed above it. The dynamometer consists of a piston or plunger working in a vertical cylinder containing oil and water. The piston rod extends downwards outside the cylinder, and is bolted to the bracket carrying the pulley spindle. Any strain on the cable, therefore, raises the pulley, bracket, rod and piston, and is indicated by a pointer on a vertical scale (not shown). The cable then passes over the stern sheave into the sea. While paying out in this manner, the brake on the paying out drum forward is regulated from the bridge, as before described, so as to keep the strain indicated on the dynamometer as constant as possible. As the brake is regulated on the bridge platform, it would be an advantage to indicate the strain somewhat nearer the bridge, either actually or by transmission. The new gear described above has a very solid and compact appearance, and has been designed to sustain a strain of 25 tons, acting in a direct line from the drums. This is considerably above what is usually met with in cable work, and the gear is, moreover, capable of bearing double that strain, so that an ample margin is provided for.

ON A BALLISTIC ELECTROMETER.*

The quadrant electrometer can be used ballistically if the usual damping arrangement is removed, and the needle suspended by a conducting wire. The impulse given to the needle by a moment M acting for a very short time is equal to $\int M\,dt$; and as M may be made proportional either to V or V^2, where V is the potential difference between the quadrants, it thus becomes possible to measure $\int V\,dt$ and $\int V^2\,dt$. Thus if the needle is charged to a high constant potential, the magnitude of the first swing is proportional to $\int V\,dt$; and if the quadrants are connected with the two terminals of a resistance R through which a quantity Q of electricity passes in a very short time it is easy to see that whatever the self-induction of the resistance R

$$\int V\,dt = R\,Q$$

This formula has been practically tested with a Mascart electrometer, whose needle was suspended with a platinum wire 0·02mm. in diameter, and charged to a potential of 300 volts. With this instrument a discharge of one microcoulomb through a megohm gave a deflection of 130mm. on a scale two metres off, the period of the needle oscillations being 11·6 seconds. It is necessary that the capacity of the condenser used for the discharge should not be too high, or the time taken for the discharge will prevent the electrometer acting ballistically. The action is, however, satisfactory if the product of the capacity in microfarads and the resistance in megohms does not exceed ⅟₁₀th.

In this way large resistances may be conveniently measured, and, as very small quantities of electricity are used, the method is especially suitable for liquid resistances, where difficulties usually arise from polarisation. If, instead of Q being known, R is known, the method is one for measuring electrical quantity; and the electrometer thus does the duty of a ballistic galvanometer. The sensibility may, however, be made very great by giving a high value to R. By a suitable modification of the method, condensers of widely different capacities may be compared, and by connecting the needle to one pair of quadrants the electrometer may be used as a ballistic electro-dynamometer.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, June 27th.

SOCIETY OF ARTS.

9 p.m. Conversazione at Natural History Museum, South Kensington.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

* Abstract of a Paper by M. Gouy, *Comptes Rendus*, June 2, 1890.

Digitized by Google

The Electrician.

shed every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and be crossed* "*Coutts and Co.*"

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

PROSPECTS OF ELECTRIC TRACTION.

The recent transformation of two comparatively small concerns connected with electric traction into a single large company with a somewhat inflated capital, and the announcement that a still larger call is about to be made on the public in order to develope the Thomson-Houston and Series systems in Great Britain, lead to the hope that something comparable to the rapid progress of electric traction in the United States may be shortly witnessed in this country. Perhaps the most satisfactory feature of the last-mentioned project is the statement that contracts have already been entered into to the extent of about three-quarters of a million for equipping tramways in various parts of the country. From this we are led to expect immediate solid work, and not months or years of preliminary experimenting, which a visit to the United States by a competent engineer should now render quite unnecessary. When our English inertia—which, as Prof. AYRTON neatly puts it, may be defined as resistance to motion as distinguished from

Digitized by Google

resistance to stopping which characterises the inertia of our transatlantic cousins—has been once overcome, we have but little doubt that the electric tramcar will become as familiar an object in our streets as the ubiquitous omnibus; and although the preference will be largely for accumulator conduit or sectional conductor systems, yet, if the English prejudice can anyhow be removed, we should not be surprised to see a very respectable mileage on the overhead system.

If, however, electric traction is to exhibit that rapid and, above all, that healthy development which we all hope it will do, there must be no repetition of the tactics which brought so much discredit and disaster upon electric lighting in the early days of its introduction into this country, and which made the term "pioneering electric lighting" synonymous with everything that should not be. The evils of over-capitalisation, and of paying huge sums for patents of doubtful validity and but small practical utility, have already been ably dealt with in the columns of a contemporary. But there is another point of scarcely less importance upon which much and painful experience was gained some six or seven years ago. Electric lighting, when it first attempted to establish itself upon a commercial basis in this country, had to fight a rival illuminant which was admittedly much cheaper, and was in those days undoubtedly steadier and more reliable if not quite so brilliant. Under those circumstances it was perhaps too much to expect that the first electric lighting contracts should have been taken only at remunerative prices. Even at the present time the cheapness of gas is a standing temptation to contractors to undertake lighting, and especially street lighting, at prices which, if the work were carried out on an adequate scale with an ample reserve of engine power, would leave but the barest margin of profit.

Whatever good this system of taking on contracts at unremunerative prices may have done to electric lighting, has been outweighted, we feel sure, by the harm it has wrought in other ways; and the same considerations apply also to electric traction. If the figures brought forward from across the Atlantic are to be trusted—and we see no reason to question their general accuracy—electric traction, without taking into consideration its indirect advantages, is undoubtedly cheaper than horse or cable traction. In England, no doubt, several of the factors which go to make up the total cost of electric traction per car mile run would have to be modified; but the comparative cost of electric and horse traction will not, we think, be found to be perceptibly affected. There should therefore, in the case of electric traction, be no repetition of the mistaken policy of offering to do work at a price which does not pay, in the hope that, once in possession of the business, past losses may be recouped by enhanced prices. Although the lengthy correspondence which recently appeared in our columns, on the disputed point whether 4½d. per car mile was or was not a paying price for accumulator traction, left the question very much where it was, the conclusion generally arrived at was that even on a large scale the margin of profit would not be very satisfactory. British taste, there is reason to fear, will not permit of the stringing of wires like clothes lines along the streets, and drawing off the current by means of contrivances resembling fishing rods fastened to the roof of the cars. That may be and probably is the case; but until either a really workable underground system is in the field, or British taste has been educated up to the overhead system, we fail to see what permanent good can accrue to electric traction by working accumulator or any other kind of cars at unremunerative rates.

Another feature of early electric lighting, one indeed which has not been quite got rid of—if we may judge by some rose-coloured estimates of a leading London firm of contractors recently laid before a Local Board—is the dazzling of Local Authorities and others with unrealisable visions of huge profits. This device is also one which we trust it will not be found necessary to make use of in pushing electric traction. Electricity as a motive power has a large field in England, larger indeed than many suspect; and since, if properly worked, electric traction is less costly than its rivals, it behoves those who are connected with it to develop it by sound financing and honest estimating.

THE INTERNATIONAL TELEGRAPH CONFERENCE AT PARIS.

At last the Seventh International Telegraph Conference has come to an end. Opening on Friday, May 16th, the Convention was signed on Saturday last, June 21st, having thus lasted thirty-seven days, or two days less than the last Conference at Berlin. The propositions for alteration of rules put forward by various Administrations covered 137 pages of print; but very little has been done which affects the public.

The first thing discussed in the Tariff Commission was a proposition of Germany for a uniform tariff throughout Europe of 2d. per word, which would have involved a heavy loss to all the Companies and most of the Administrations. After an exhaustive debate, the proposition was deferred for consideration at the next Conference, which is to be held at Budapest in 1895. The proposal made by Germany to double the price of code words, that of Austria insisting upon ten words as a minimum in a telegram, and that submitted by Great Britain recommending five words as a minimum, were rejected.

It may be mentioned that the Berne Office has been instructed to prepare a vocabulary containing legitimate words in the eight languages authorised for code correspondence. Three years after the publication of this vocabulary it will be compulsory for the public to choose from it the words they require for code correspondence. This rule will, however, only apply to telegrams sent within the European régime; for messages sent over extra-European lines the Telegraph Administrations concerned have the option of putting the rule into force or not at their discretion. The idea of an authorised vocabulary has long had for its principal supporter Sir James Anderson, the Managing Director of the Eastern Telegraph Company, and it will tend to abolish the constant bickerings over doubtful words which now take place between the public and the Telegraph Administrations. Another advantage is that the operators will get accustomed to the words contained in the authorised vocabulary, so minimising the risk of error in and possibly accelerating the speed of transmission.

As regards reductions of tariff, various reduced rates will come into operation on July 1, 1891, viz., Great Britain to Spain will be 4d. per word, instead of 4½d., and the rate to Portugal and Gibraltar will be reduced from 5½d. to 4½d. per word. Other small reductions will also take place to the Northern countries of Europe, and there will be a reduction of ½d. per word to Greece. The rules and regulations adopted by the Conference are embodied in the "International Telegraph Convention of Paris, 1890," which, until revised by the next Conference, will be the authority as between the Administrations themselves and the Administrations and the public on all questions relating to international messages.

At the final sitting of the Conference, Sir John Pender announced that it was expected that the tariff to Australasia would be reduced from 9s. 4d. to 4s. per word, under a guarantee of revenue from the Australasian Colonies, the negotiations for which were almost complete. It is proposed to bring the reduced tariff into operation on January 1, 1891.

One of the most interesting incidents of the Conference was the presentation, by the Minister of Commerce, Industry, and the Colonies, of the Commandership of the Legion of Honour to M. Nielsen, the Norwegian delegate, who was

Digitized by Google

the only delegate at the Paris Conference of 1890 who was present at the Paris Conference of 1865.

As a means of bringing the delegates together socially and so enabling them to soften down the various differences of opinion which arose in the public meetings, the different receptions, dinners, and excursions had a most salutary effect. They may be summarised as follows: A reception and garden-party given at the Elysée by the President and Madame Carnot; a dinner and three receptions given by the Minister of Commerce, Industry, and the Colonies, and Madame Jules Roche; pleasant excursions to the Château of Pierrefonds, with a drive back through the wood to Compiègne; and a day pleasantly spent at Versailles. Also a three-days' trip to Rouen and Havre, with banquets given to the delegates by the Municipality and Chamber of Commerce at each place. The party was conveyed by steamer from Rouen to Havre, thus affording an opportunity of seeing the picturesque scenery of the Lower Seine. M. Jules Roche, the Minister of Commerce, under whose department the posts and telegraphs are placed, also supplied the delegates with tickets for two performances at the Opéra and Opéra Comique. The French Companies gave a dinner at the Eiffel Tower, with an ascent to the top at midnight, where some members of the Conference sung with vigour the national anthems of their respective countries. The breakfast given by the foreign Telegraph Companies at the Hôtel Continental, under the presidency of Sir John Pender, has already been reported at length, and was decidedly one of the most successful entertainments during the whole Conference. Visits were also paid to the sewers and catacombs of Paris.

In closing, a word must be said in praise of M. De Selves, the Director-General of Posts and Telegraphs, who was the President of the Conference, and conducted all the proceedings with urbanity and decision. The State delegates and the representatives of the Companies both presented him with testimonials in the shape of works of art as a souvenir of the meeting. Testimonials were also presented by the Companies to M. Eschbaecher, the secretary of the Conference, and the assistant-secretaries, MM. Gramaccini, Morel, Forestier, Frouin, Bordelongue, and André.

THE ELECTRIC LIGHTING OF BATH.

The inauguration of the public lighting of Bath took place on Tuesday, the 24th inst. The Mayor switched on the lights at 9 p.m., in the presence of a distinguished company of Bath residents and representatives of the Press, after which a supper was given by Mr. Massingham at the Grand Pump Room Hotel to celebrate the occasion. In the speeches which followed the supper, Mr. Massingham's name was duly eulogised for the indomitable energy and persistence which have resulted in the establishment of an electric supply in Bath. How little of the credit of having established the station is due to Bath, and how much to Mr. Massingham, is best seen by the fact that the efforts to form a local company failed, although powers to commence a supply had been secured. Mr. Massingham then boldly determined to put down the works at his own expense.

In the first instance it was proposed to erect the station on a site having water-power; but the power available having been found to be insufficient, the present situation was decided upon in preference. We are informed, however, that it is still intended to secure the former site, and to utilise the water-power for the day supply and hours of light loads. The site selected adjoins the Great Western Railway Station, and has a frontage in Dorchester-street; on the other sides it is bounded by the Avon and a carrier company's premises. Being also close to the main thoroughfares it is on every count an excellent position for an electric supply station.

The original premises—formerly used as a flour mill—constitute the offices and caretaker's house, and light and airy buildings have been erected over the yard abutting on the river for the boilers and machinery. The boiler-house is 40ft. by 90ft., and capable of extension to a length of 120ft.; the engine and electric machinery house is 40ft. by 113ft., and can be extended to 150ft. When these limits are reached, the buildings will accommodate plant for a supply of 300 arc lamps and 30,000 10 candle-power incandescents.

The plant units adopted are:—Babcock and Wilcox boilers of 150 horse-power, working at 150lbs. per square in. pressure; 75 kilowatt Mordey alternators, rope-driven by Raworth vertical compound engines, constructed by the Brush Electrical Engineering Company; and 50-light Thomson-Houston 6·8 ampere arc dynamos, belt-driven by Raworth vertical compound engines. The Thomson-Houston plant has been supplied by Messrs. Laing, Wharton and Down. No counter-shafting is employed, the engines and dynamos being equal in number, and each engine constructed to be economically loaded by its own dynamo when connected to the supply mains. The condensing arrangements are not yet in operation, owing to a defect in the circulating pump; but the plant already put down, consisting of one surface condenser and circulating and air pumps, are stated to be equal to the requirements of the present plant. At present there are two boilers in position, and two sets of engines and 75 kilo-watt alternators, and two more of each of the foregoing are to be delivered by September 1st. The number of arc sets already installed is four.

The boilers are supplied with feed-water by a Dean pump, and injectors have been fitted to each as stand-byes; the latter, however, are found to be practically useless on account of the large amount of deposit from the water, which is continually causing them to fail; and a second pump is consequently being put in as a safeguard. The steam is carried from the boilers by 5in. pipes into a 6in. main, which runs lengthways along the engine-room. The latter is divided into sections by valves at intervals, so that in case of accident a section can be shut off from the boilers, and independent connections are to be made in the boiler-room so as to minimise the amount of plant disabled by any accident to the steam piping.

The engines which drive the alternators are capable of indicating 150 horse-power, and run at 185 revolutions per minute; they are fitted with screw gear, worked by a hand wheel, for varying the cut-off; while what may be called the fine adjustment is made by a Hindley governor operating a throttle valve. We believe that these engines are the first, or nearly the first, which have been constructed by the Brush Electrical Engineering Company of this size. So far they have given complete satisfaction; they have a first-class appearance, and the simplicity of the design, and accessibility of all the working parts to the attendant, should enable him to detect the slightest irregularity at once, and so lessen the chance of an accidental stoppage. Beyond putting down good solid foundations no precautions against vibration have been necessary, owing to the nature of the surrounding property.

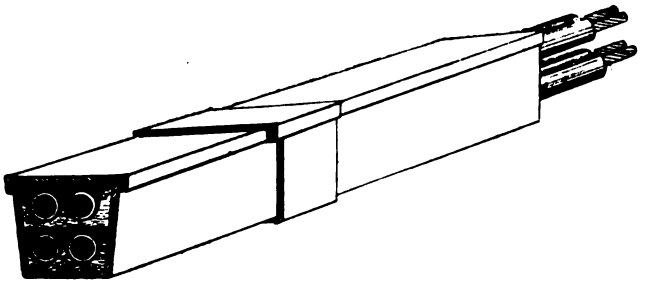
The alternators run at 500 revolutions per minute, and give an E.M.F. of 2,000 volts, and a current having a period of 100 $\sim$ per second. Constant circulation of the oil is maintained through the bearings by means of small rotary pumps, driven by light bands from the dynamo shaft. The high-tension mains rise vertically from the dynamos, after which they cross over to the wall and descend to the switches and instruments. Each machine is provided with a switch, which consists of two independent levers, hinged at one end, and fitting in between two copper brushes at the other; a spring at each hinged end causes the levers to fly out from between the brushes, unless secured by a catch. The levers are pulled down by two cords, to which a ring is attached, and the catches snap over their ends. Two other cords are attached to the catches, by pulling which the levers are released and fly out, breaking the circuit. A lad is employed to keep the volts constant, and to register the outgoing current. The volts are indicated by a Cardew voltmeter connected to one coil of the armature, and registers $\frac{1}{24}$th of the total E.M.F. The lad varies the volt by means of a sliding contact, which rubs on the coils of a platinoid resistance connected into the exciting circuit.

The engines which drive the arc machines are of 35 horse-power; and the Thomson-Houston dynamos are fitted with a switch, which, by short-circuiting the armature, enables the lights to be turned on or off without the inconvenience and danger which attaches to making or breaking the high-tension current.

Digitized by Google

The mains are laid entirely underground on Callender's solid system, which consists in laying the cables in iron troughs, in which they are supported at intervals by wood bridges. When the cables are in position molten bitumen is poured in until the troughs are full, and the whole is covered in by a cast iron lid.

The annexed figure gives a perspective view and section of the main. It is said that there are 30 miles of cables, and that the insulation resistance of the whole when connected up was 30 megohms. There are three independent sets of mains. The first set is for distributing the alternating high-tension current, and consists of eight pairs of feeders, each of 19/16's, which run to the distributing centres. Each pair of feeders has its own distributing network which is not connected to the rest; but cables of sufficient section to carry the whole current run from the distributing centres to points situated between the adjacent networks; so that in case of any accident to a pair of feeders, or repairs being necessary the network fed by them can be coupled up with the adjoining networks and supplied from them in the meantime. Eventually it is intended to connect the alternators in parallel at the station; but the networks will be kept distinct from each other, so as to confine the disturbance which might be caused if an earth or short-circuit occurred—through the pickaxe of a careless but powerful British labourer, for instance—to the locality in which the accident took place. The second set of mains supplies the private consumer's arc lamps, and the third the arc lamps employed in lighting the streets.



The mains have been laid by Callender's Bitumen Telegraph and Waterproof Company (Limited), under the superintendence of Mr. W. Douglas Reid, the Company's resident engineer.

Mordey transformers are employed to provide an E.M.F. of 100 volts on the consumer's premises. We noticed one large installation of about 250 lamps of 20 candle-power, where the lamps are of Woodhouse and Rawson's make; and the report given us was that this firm's lamps were very efficient and durable. The arc lamps (Thomson-Houston) used by private consumers are chiefly employed outside to light the windows of shops, &c. They are in all cases trimmed by the supplier's servants. There are at present 31 arc lamps supplied to private consumers, each of 1,200 candle-power. The street lamps are also of 1,200 candle-power, and are suspended from neat cast-iron posts. The lamps themselves are suspended by a flexible concentric cable, which passes over pulleys fitted into each corner of the bracket arm. The cable passes down the inside of the post to within about 6ft. of the ground, where it terminates in a wedge connector. A counter-balance weight is attached to the cable just above the connector. When the lamp is up in position for burning, the wedge connector is pushed in between two copper brushes connected in the main circuit, by which means the brushes are separated and the current diverted through the lamp. When it is required to lower the lamp for trimming or cleaning, a cord is attached to a hook at the end of the cable, the wedge connector is pulled out, and the lamp descends by an excess of weight over the counter-balance. When the connection is withdrawn, the brushes close together and complete the main circuit. It will thus be seen that the lamps are entirely detached from the high-tension mains except when in position for burning. This arrangement has been worked out by Mr. G. S. Hooker, Mr. Massingham's electrician in charge. The street circuits are two in number, and supply a total of 81 lamps. They are distanced an average of about 90 yards apart; and the general effect about the centre of the town is very good indeed, the Thomson-Houston lamps burning with their accustomed steadiness.

The charge made to private consumers is 6s. per annum for each 10 candle-power lamp wired, the consumer being free to burn his lamps as many hours as he pleases. The necessary check on careless and wasteful burning is provided by the cost of lamp renewals, which the consumer has to meet. Arc lamps are charged for at the rate of £8 per annum if burning from sunset to 8 p.m.; £9 if burning till 9 p.m.; £10 if burning till 10 p.m., and so on. Lamps situated inside of buildings are charged £1 per annum extra. The prices include trimming and cleaning and carbons, but not globes.

The contract with the Corporation, which is of seven years' duration—comes out at about £26 per lamp per annum, and includes trimming and cleaning and finding carbons and globes. The hours of lighting are sunset to sunrise all the year round.

It may be mentioned that the Bristol coal dues raise the price so much that it is found cheaper to get the coal supply by rail. The price now paid is 14s. per ton.

The alternating plant has now been supplying incandescent lights for about three months, and there are about 3,000 lamps wired. It is found that at this time of the year the maximum demand seldom exceeds one quarter of the amount it would reach if all the lamps were turned on at once.

Mr. Massingham must be congratulated on the successful start which has been made, and on the sound and healthy appearance of things both inside and outside of the station.

THE NEW LINEFF SYSTEM OF ELECTRIC TRACTION.

More than two years ago we published a brief description of the Lineff and Jones system of traction. This system, it will be remembered, was of the "conduit" class, the most novel feature being the method of making contact between the car and the underground conductor. A bare copper wire was run inside a gas pipe, into which iron forks were screwed every few feet, their ends clamping down on the copper wire inside, and ensuring a good contact. A flat iron plate at each end of the car ran in the central slot. Between these plates and inside the conduit hung a flexible conductor, consisting of brass "beads," strung on a stranded wire cable. As the car moved along this flexible conductor rested on the forks in the gas pipe never making contact with less than four at once. This system we believe, never got much beyond the experimental stage.

The system now adopted by Mr. Lineff, a demonstration of which was given on Wednesday at the Chiswick High-road Depôt of the West Metropolitan Tramway Company, is on what may be termed the sectional conductor principle. A few inches inside one of the rails are arranged insulated sections of girder iron, 3ft. in length, and embedded in asphalte, the upper flat surface of the iron being level with the roadway. A small channel runs along inside the asphalte under the iron. At the bottom of this channel a flat bare copper conductor rests on china insulating bridge pieces. Upon the top of the copper conductor, and about $\frac{5}{16}$in. beneath the surface conductor, forming the roof of the closed conduit, lies a substantial strip of iron. The car is fitted with a powerful electro-magnet, the cylindrical core of which is somewhat longer than a section of the surface conductor. The pole-pieces of this electro-magnet are spread out considerably, and lie just over the surface conductor, between which there is about $\frac{1}{16}$in. clearance. The magnet is energised by the main current, its coils being in parallel with the motor. As the car moves along the track the magnetic circuit of the magnet on the car is completed through the surface conductor and the iron strip in the channel underneath; the strip is consequently lifted up into contact with the surface conductor, thus completing the electric circuit between the underground main through the motor to the return rails. As only two sections of the surface conductor are "charged" at one time, the "live" sections are always under the car. The current is taken off by means of a small wheel and a brush

Digitized by Google

fitted on to each pole-piece of the electro-magnet, the weight of which being some hundredweight, ensures good contact. The car operated on Wednesday was a light open one. It was fitted with a 4-horse power Immisch motor and magnetic brake, the current being supplied at a pressure of 240 volts by an Immisch dynamo.

Mr. Lineff, it will thus be seen, has avoided the use of innumerable electro-magnets for the purpose of bringing the successive sections of his surface conductor into play, and has thereby considerably enhanced the practical value of the closed-conduit system. Whether he has steered clear of previous patents remains to be seen. But, in any case, it is to be hoped that Mr. Lineff's new system will reach a higher stage of development than the one referred to at the beginning of this notice.

THE ELLIOTT SMOKE ANNIHILATOR.

On Wednesday last we paid a visit to Newbury, in response to an invitation to view a Smoke Annihilator which has been devised by Mr. Samuel Elliott, of the Albert Moulding Mills and Joinery Works, Newbury. In this apparatus, the smoke is drawn from the flue by a fan, and by the same means is driven through the machine, or "Annihilator."

The "Annihilator" consists of a square cast-iron tank, in which is mounted a hollow cast-iron cylinder capable of revolution on its axis. One end of the cylinder is closed, and a pivot is provided which fits into a bearing in the end of the tank. The cylinder is continued through the other end of the tank, and supported by a packed bearing or stuffing box. The protruding end of the cylinder carries three pulleys—a driving and a loose one, and one from which the fan is driven. The end of the cylinder is connected to the discharge opening of the fan. Inside the tank the cylinder is drilled with numerous holes about 1in. in diameter, and a number of blades are attached to its periphery extending the whole length of the tank, and of such width as to just clear the sides and bottom of the tank as they revolve. The blades are made of iron sheet, perforated with holes about ⅜in. diameter, the holes being almost as close together as the metal will stand.

When the machine is in operation the tank is filled with water about up to the level of the centre of the cylinder, and the cylinder is revolved at a speed of about 150 revolutions per minute. The smoke is driven into the cylinder by the fan, with a certain amount of steam added—which may be a portion of the exhaust from an engine—and passes out through the holes in the cylinder and encounters the water; it is, in fact, thoroughly mixed up with it by the revolution of the perforated iron blades. The result is that the water becomes of a brownish colour, and a thick black scum accumulates in the top part of the machine, from whence it is drained off into suitable receptacles by sloping channels ending in spouts on each side. A perfectly white vapour issues from the funnel on the top of the machine, which is quite inodorous, and vanishes in the air like steam, which it doubtless is.

The machine shown in operation was connected to a marine boiler of about 100 horse-power capacity; the fires were made to smoke badly, and when a dense black volume was issuing from the chimney the "Annihilator" was put to work, the result being that the black smoke was immediately replaced by perfectly white vapour.

The experiments were not quantitative, so that it was impossible to form a very useful opinion of the commercial value of the invention. That the machine is capable of annihilating smoke there could be no manner of doubt; and if it is found not to absorb too much power when dealing with the large volumes of products of combustion emitted from the flues of a large central station or manufactory, and not to be too costly in itself, there certainly should be a good field for it. On the important point as to how much power has to be expended in the "Annihilator" to deal with a given quantity of smoke, the only information we have is the statement that about 2 horse-power is required to "annihilate" the smoke coming from the furnace of an ordinary 60 horse-power boiler.

We should very much like to see one of Mr. Elliott's machines put into every-day work, say, in connection with one of the London Central Stations, where its capabilities and the cost of operating it could be accurately determined.

The following details of the composition of the dry scum, from a report by Mr. C. W. Heaton, may prove of interest:—

Composition of Dry Scum in 100 parts:—

THE MEASUREMENT OF L WITH A CARDEW VOLTMETER.

The following method of measuring L, due to Mr. W. Brew, may prove of some use when the usual reflecting galvanometer, &c., are not at hand. It simply consists in placing the inductive coil or resistance, whose coefficient of self-induction is to be measured in series with a Cardew voltmeter or other instrument of high resistance, whose deflections measure

$$\sqrt{\frac{1}{T}\int_0^T i^2\,\delta t}$$

or the square root of the mean square of the current passing through it; and measuring the apparent resistance of this inductive coil by means of two deflections of the voltmeter (one being obtained with and the other without the inductive coil in series) when in circuit with an alternating potential difference of known periodicity. The apparent resistance, r_1, of the coil is

$$r_1 = \left(\frac{D_2}{D_1} - 1\right) R \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

R being the resistance in ohms of the voltmeter,
D_1 and D_2 being the respective deflections upon it, with and without the coil in series. Also,

$$r_1 = \sqrt{r^2 + \frac{4\pi^2 L^2}{T^2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

r being the resistance in ohms of the coil measured in the ordinary way on a Wheatstone's bridge,
L being the self-induction coefficient required,
T being the time in seconds of a complete alternation,
From (2) we have:—

$$L = \frac{T}{2\pi} \sqrt{(r_1^2 - r^2)} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

or, substituting for T the number of alternations per second n,

$$L = \frac{\sqrt{(r_1^2 - r^2)}}{2\pi n} \quad . \quad . \quad . \quad . \quad . \quad (4).$$

The following test of a bobbin 5½in. in length, inside and outside diameter 1in. and 2in. respectively, convolutions about 9,000, and having a resistance of 326ω, may serve to illustrate the method:—

D_1.	D_2.	$\frac{D_2}{D_1}$.	r_1.	n.	$\frac{\sqrt{r_1^2 - r^2}}{2\pi n}$	Remarks.
20·8	65·2	3·134	342·7	58·13	0·435	The resistance of the voltmeter in this experiment was 170ω.
22·0	70·8	3·218	377·0	63·8	0·472	
24·5	77·8	3·176	370·0	58·0	0·480	
18·5	58·2	3·22	377·4	63·8	0·474	

Digitized by Google

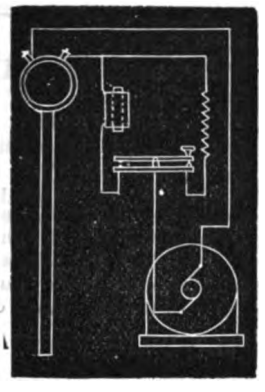
In some cases it may be convenient to employ a non-inductive resistance in series with the voltmeter of resistance equal to the coil to get the ratio $\frac{D_2}{D_1}$ to suit the range of the instrument; this resistance is represented in the sketch by the zig-zag line at the right key; with this arrangement we have in the equation

$$r_1 = \left(\frac{D_2}{D_1} - 1\right) R$$

r_1 equal to $\sqrt{4\pi^2 L^2 n^2}$ alone, and R equal to the resistance of the voltmeter plus the non-inductive resistance. Consequently

$$L = \frac{r_1}{2\pi n} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

which we also get directly from equation (4) by putting $r = o$.



In the above formula, the difference in phase of the potentials on the coil and on the Cardew instrument is neglected. If this is taken into account, a slight change in the formula is necessary. We then have—

$$\frac{D_2}{D_1} = \frac{\sqrt{(R + r)^2 + 4\pi^2 n^2 L^2}}{R} \quad . \quad . \quad . \quad . \quad (6)$$

or

$$L = \frac{R}{2\pi n}\sqrt{\frac{D_2^2}{D_1^2} - \left(\frac{R + r}{R}\right)^2} \quad . \quad . \quad . \quad (7)$$

R being the resistance of the Cardew voltmeter,
r being the resistance of the induction coil.

ON THE HEATING EFFECTS OF ELECTRIC CURRENTS. No. IV.*

BY W. H. PREECE, F.R.S.

The effects of the heat developed in conductors when electric currents are transmitted through them have been the subject of constant investigation on my part since 1878. In 1880 I found that the rapidity with which small bare wires acquired higher temperatures and lost them in air was so great that it was possible to reproduce sound and speech by means of the thermo-telephone (*The Electrician*, June 5, 1880, p. 32; Roy. Soc. *Proc.* No. 204, 1880). I determined subsequently (*The Electrician*, April 12, 1884, p. 518; Roy. Soc. *Proc.*, No. 231, 1884) the current that raised the temperature of small conductors in air to the fusing point, and proved experimentally that, while bare cylindrical wires of very small diameter did not follow the $d^{\frac{3}{2}}$ law, this law became rigid for all diameters above 1mm. Papers (Roy. Soc. *Proc.*, November 24, 1887, and March 15, 1888; *The Electrician*, February 17 and 24, 1888, and April 27, 1888) dealt principally with the fusing points; and the following table, to which I have added silver, gives the fusing constants for all the metals in general use when bare and exposed in still air. The numbers indicate the current in amperes which is required to fuse a cylindrical conductor of a diameter of 1cm. of the material named.

* Read before the Royal Society.

—	Fusing constant (a).	Fusing temperature C°.
Copper	2530	1054
Silver*	1900	954
Aluminium	1875	650
German silver	1292	1200
Platinum	1277	1775
Platinoid	1173	1300
Iron	777·4	1600
Tin	405·5	226
Lead	340·6	335
Alloy (lead 2 parts, tin 1 part)	325·5	180

I have added the temperature of fusion of each of these metals; and the table means that if we take, for example, a uniform copper wire of (d) cm. diameter, the current in amperes needed to raise it to 1,054° C, and therefore to fuse it, is given by the equation

$$C = 2530 d^{\frac{3}{2}}.$$

It seemed natural that these constants, marking such a distinct and well-defined fiducial point, should also enable us to obtain the currents that would raise the wire to any other temperature.

A constant current traversing a cylindrical metallic conductor does work upon that conductor to an amount which is measured per second by the product of the electromotive force (E) at the end of the conductor and the current (C). This work appears as heat. The temperature of the conductor is raised. When the temperature of the wire becomes constant the expenditure of energy in the wire, and its dissipation by radiation and convection from the surface of the wire, must be equal and constant also. Hence the temperature of the conductor when constant becomes a measure of the work done per second, and therefore a measure of the constant current flowing. The rate of loss of heat per degree per unit area of any surface is its emissivity (e). The value of e depends upon the character of the surface, that is, whether it is polished or rough, clean or dirty, bright or black, metallic or oxidised, painted or coated with some preservative or insulating medium. For the present we will consider an unprotected surface comparable with the surface when at white heat, and we will call that surface *normal*. Let a current be applied to a given conductor, exposed in still air at atmospheric pressure, until it assumes any constant temperature, which is (θ) degrees in excess of that of surrounding objects, then the total heat which will be emitted per second by the whole surface (S) of the wire to the surrounding objects will be $eS\theta$, and this must be equal to the heat generated by the current.

Hence $$EC = eS\theta, \text{ or } e = \frac{EC}{S\theta}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Hence we can determine e for any conductor at any temperature by measuring E C and θ.

Putting $E = C R$, $S = l \pi d$, and $R = 4\rho l/\pi d^2$ (ρ being the specific resistance in C.-G.-S. units, l the length, and d the diameter in centimetres), (1) becomes

$$4 C^2 \rho = e \pi^2 d^3 \theta, \text{ and } \theta = \frac{4 C^2 \rho}{e \pi^2 d^3} \quad . \quad . \quad . \quad . \quad (2)$$

Now, if ρ and e vary together in the same proportion in terms of θ, then $\theta = \kappa C^2$ for any particular wire. That ρ and e do vary together in the same proportion is entirely in accordance with measurement and experiment; and it is interesting to note that it is also in accordance with the researches of Mr. J. T. Bottomley on thermo-radiation (*Phil. Trans.*, Vol. 178 (1887), A, pp. 429—450). Thus, if we take the table given on p. 443 of that Paper, and work out the variation in resistance of a platinum wire (which variation is the same as for copper) by the usual formula,

$$R_t = R_0 (1{\cdot}0038)^{\theta},$$

we get the values shown in the fourth column:—

Bottomley's researches.			R_t calculated from the formula $R_t = 14{\cdot}5\ (1{\cdot}0038)^{\theta}$.
θ.	C^2/RJs.	e.	
65°	$9{\cdot}45 \times 10^{-4}$	$14{\cdot}5 \times 10^{-6}$	14·5

*G. Roux, 'L'Électricien,' December 14, 1889.

Digitized by Google

If we determine C for any temperature, then, since $\theta = \kappa C^2$, the current C′ producing any other temperature θ' is obtained by means of the equation

$$C' = C\sqrt{\frac{\theta'}{\theta}}$$

Now, for copper of 1cm. diameter C = 2530 for 1054°. Thus, if we want to find the current that will raise such a conductor to 13°, we have

$$C' = 2530\sqrt{\frac{13}{1054}} = 281 \text{ amperes,}$$

if the surface be equivalent to the assumed normal surface.

Now, since we are dealing with metallic surfaces only, and the normal surface has been defined to be that comparable with the surface when at a white heat, it remains for us to determine the coefficient which shall convert this normal-surface emissivity to that of the surface of ordinary wires at low temperatures. This I have done for copper; and the results have been amply confirmed by Mr. Kennelly, in Mr. Edison's laboratory at Orange, N.J., U.S.A.*

Taking the normal surface as unity, then

	Surface coefficient
Bright and polished copper	0·5
Copper, dirty, oxidised, or blacked with shellac varnish	0·6
Copper, well coated with lampblack	1·0

Taking a wire 1cm. in diameter and calculating from $C' = 0{\cdot}5C\sqrt{\frac{\theta'}{\theta}}$ for bright wire, and $0{\cdot}6C\sqrt{\frac{\theta'}{\theta}}$ for black wire, we get a concordance which is very satisfactory.

5°.				10°.				20°.			
Bright.		Black.		Bright.		Black.		Bright.		Black.	
P	K	P	K	P	K	P	K	P	K	P	K
87	85	104	104	123·2	120	148	147	168	169	201	207

40°.				80°.			
Bright.		Black.		Bright.		Black.	
P	K	P	K	P	K	P	K
243	236	291	290	350	329	420	410

N.B.—P means calculated from the formula $C' = 1265\sqrt{\frac{\theta'}{\theta}}$, and K means the figures obtained by Mr. Kennelly.

Now, the current (C) producing 1054° (θ) in a bare bright copper cylinder of 1cm. diameter is $0{\cdot}5 \times 2530$ amperes, and that which would produce a temperature of 10° C. is

$$0{\cdot}5 \times 2530\sqrt{\frac{10}{1054}} = 123{\cdot}2 \text{ amperes.}$$

Using both alternating and continuous currents, it was found that in a copper wire with $d = 0{\cdot}6956$, θ was 50°·3. Now the current (C) that will raise a wire 1cm. in diameter 50°·3 in temperature is

$$C' = 2530\sqrt{\frac{50{\cdot}3}{1054}} = 552{\cdot}7 \text{ amperes.}$$

But the current that will raise a wire of a diameter of 0·6956cm. through the same temperature is

$$(C \times d^{\frac{3}{2}}) = 552{\cdot}7 \times {\cdot}6956^{\frac{3}{2}} = 320{\cdot}6 \text{ amperes;}$$

or, if the wire be dirty,

$$320{\cdot}6 \times {\cdot}6 = 192{\cdot}4 \text{ amperes.}$$

The current actually was in each case 198 amperes.

A copper conductor, bare and dirty, 20 feet long and 0·415in. in diameter, was stretched across a room where the air was still, and various continuous currents were transmitted through it. The results are tabulated, and the observed and calculated currents given :—

Time.	Increase of temperature of wire C.	Current in amperes. Observed.	Current in amperes. Calculated. $C' = 0{\cdot}6\,C\sqrt{\frac{\theta'}{\theta}}/d^{\frac{3}{2}}$.
10·45		454	
11·15	86°	454	467·7
12·0	80	450	451
3·30	79	445	448
3·45	78	440	445
4·30	73	429	431
Current stopped; wire cooled. Current put on again at 5.30.			
6·0	38	290	310

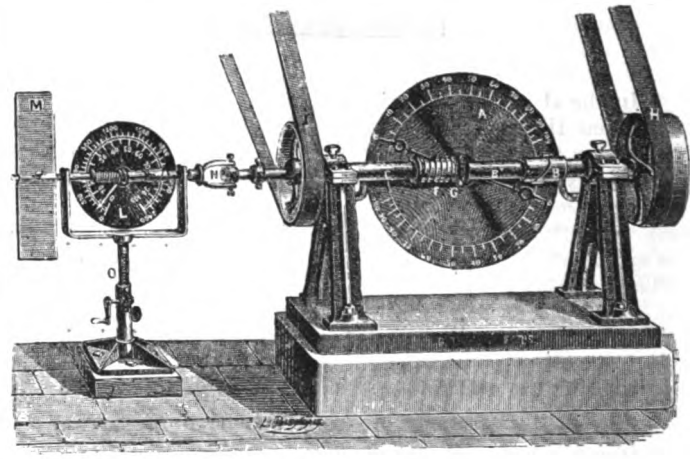
Thus, if we know the current producing any fixed temperature in any cylindrical conductor, we can readily calculate the current required for any other temperature.

* A. E. Kennelly, "On the Heating of Conductors by Electric Currents" (*Electrician*, December 13, 1889), *et seq.*

THE TROUVÉ DYNAMOMETER.*

The following is a brief description of a simple dynamometer designed by M. G. Trouvé, which can be used either as an absorption or transmission instrument.

Power may be considered either as the product of the force exerted and the speed of displacement of the point of application of this force; or, again, as proportional to the product of a couple and an angular velocity. If, therefore, we can measure these two quantities separately, their product will give us the power absorbed or transmitted. M. Trouvé's dynamometer consists of two parts,



The Trouvé Dynamometer

one serving to measure the couple and the other the angular velocity. The measurement of the couple exerted is obtained by means of a flat spring arranged along the axis of the dynamometer, in order to eliminate the effects of centrifugal force. The spindle is hollow at this point, and consists of two concentric tubes. The ends of the flat spring are fixed to these tubes, which are able to follow the rotary and longitudinal movements which the torsion gives to the spring. One of these tubes carries a fixed sleeve B, cut as shown in the annexed figure. The second has a sleeve B′, free to move on it, and which is kept pressed against the fixed sleeve by the spring F, so that when the instrument is at rest B and B′ are pressed one against the other. B′ is provided with a slot, which only allows it to move longitudinally. Under the action of the torque exerted upon the axis of the system the longitudinal motion of this sleeve is utilised to rotate the indicating needle on the dial A, which is empirically graduated. In order to effect this registration the movable sleeve B′ is furnished with a deep groove, G, which engages the extremity of a bent lever connected to the needle.

The dial is graduated empirically in the following manner :—The axis of the dynamometer spring being solidly connected to one end of the shaft of a motor, a double-balanced lever is fixed to the other end. Weights are then suspended to one end until the maximum degree of torsion which it is proposed to give to the spring (180deg.) is reached. The motor is rotated at the same time, so as to keep the lever in a horizontal position. The arm of the lever is 15·92 centimetres long, so that each kilogramme applied to the end of the

* From *L'Electricien*.

Digitized by Google

arm of the level is equal to 1 kilogramme metre of work per revolution. Opposite the place occupied by the needle on the dial, the weight in kilogrammes applied to the end of the lever is marked. The lever is then unloaded, and the graduation continued.

After having tried several methods, M. Trouvé has adopted as a speed-counter an apparatus identical with that we have just described. The instrument employed by him is based upon the principle that in order to turn a rigid fan in the air it is always necessary to exert the same couple for the same angular velocity. This tachometer is shown at L in the figure.

When the apparatus is used as an absorption dynamometer, one end is fixed to the motor by means of a Cardew coupling, and the other is connected to a fan of suitable size. A graduation of the dial such as described above will enable us to read off the couples exerted. By means of a speed-counter we can estimate the angular velocity which it is necessary to give to the apparatus in order that the same needle may indicate couples of 1, 2, and 3 kilogrammetres. The product of these two indications will give the power developed. We can, therefore, mark directly on the dial the value of the power developed in the case of a given fan. Three curves obtained once for all enable us by one single observation to determine the angular velocity, the couple exerted, and the product of these two, the power. By means of different fans we can vary the power absorbed between wide limits.

The simplicity of this transmission and absorption dynamometer is a guarantee of good working, and the altogether negligible friction of the measuring organs is a reason why the indications should be exact.

RELATIVE AMOUNTS OF AVAILABLE VOLTAIC ENERGY OF AQUEOUS SOLUTIONS.*

BY G. GORE, F.R.S.

In the present research the amounts of voltaic energy were those excited by means of a zinc and platinum couple in solutions of the substances in distilled water, the electromotive force of the couple in the water alone, before addition of the substance, being equal to ·98 volt, and balanced either by a suitable thermo-electric pile (see *The Electrician*, Vol. XII., p. 414), or, much more conveniently, by an exactly similar couple in distilled water, and the substance then added in minute quantities at a time to the water of the testing cell until the needles of an ordinary torsion astatic galvanometer of 100 ohms resistance, included in the circuit, visibly commenced to move, the current from the testing cell being usually the strongest. The minimum amount of electromotive force required to move the needles was about ·00013 volt. For greater convenience in working, the two pairs of metals were attached to a frame and rack work, so as to slide up or down, and be supported either in or out of the liquids (see *The Electrician*, 1889, Vol. XXIII., p. 171). N.B.—The measurements do not include the amounts of voltaic energy lost by "local action." Each amount of energy given represents the proportion of water required to dilute one part by weight of the substance in order to make the effect upon the needles sufficiently feeble: it is also the average of two numbers, viz., one of the proportion of substance which was barely strong enough to visibly move the needles, and another of the proportion which just visibly produced that effect; the needles were observed through a magnifying glass. As the amount of mechanical work done by the current upon the needles at the point of measurement was the same in all the cases, and as all the essential conditions of action were unchanged, except the chemical composition of the liquid in the testing cell, the numbers given represent approximately the relative amounts of available voltaic energy exerted between the zinc and the respective substances in solution at the given temperatures. Polarisation was sufficiently excluded by heating the platinum to redness when necessary; the solutions used, however, were usually so extremely weak, and, by much experience in working, the point of measurement could be so quickly and nearly arrived at, that very little polarisation occurred.

As in some cases the numbers obtained varied greatly with small changes of chemical composition of the substance, they are, of course, subject to the influence of any impurity present; this influence has been separately examined. The substances employed were very generally of a high degree of purity, and any that were suspected to be impure were analysed; a large number of them had been analysed and purified from time to time. Distilled water was used in making all the solutions. In the cases were minus numbers are given the electromotive force and voltaic energy of the testing cell was *less* than that of the opposing one excited by water alone.

* Read before the Birmingham Philosophical Society.

In order to detect the influence of any invisible film of oxide, &c., formed upon the surface of the zinc in the active cell, in every instance after the determination, the active cell was emptied of solution, refilled with distilled water, and the couple immersed in the water to ascertain whether it exactly balanced the couple in the idle cell. If the two were equal, it was concluded that no interposing film had formed upon the zinc. The fact of the method being nearly a null one reduced largely the chances of polarisation.

It is evident that in such experiments only rarely, and by what is termed "accident," are the two opposing electro-motive forces perfectly equal, the particular number of pairs of the thermo-electric pile is either a little too strong or a little too weak to exactly balance the cell; or, if two cells are employed, they are never exactly alike in potential. Further, as it is highly probable that even the very smallest proportion of an acid, &c. (insufficient to move the needle), when added to the water, begins to alter the potential (see "Effects of Different Positive Metals, &c.," Roy. Soc. *Proc.*, Vol. XLIV., p. 368); then, with all proportions of substance below that which visibly moves the needles, the two opposing forces appear to be balanced when they are not so. Also, the further addition of acids, &c., not only alters the potential, but diminishes the total resistance until sufficient current passes to produce a visible movement of the needles. The question whether the two forces were sufficiently nearly balanced when they showed no effect upon the needles was tested by immersing the usual zinc wire and platinum sheet couple in distilled water, balancing its potential through the usual galvanometer by means of that of a small Daniell's cell plus a sufficient portion of the thermo pile, and allowing the arrangement to remain undisturbed during fifteen minutes to develop polarisation, and visibly change the balance; no such effect took place. In another trial the same couple was immersed in a solution of four grains of potassic chlorate and 465 grains of water; then, carefully balanced by the thermo pile and allowed to remain fifteen minutes, the balance was again not visibly altered. The extreme sensitiveness of the method is a further guarantee that the two forces were sufficiently nearly balanced when they showed no effect upon the needles.

In order to test whether the change of resistance, due to addition of acid, &c., to the couple in distilled water below the "minimum point" of change, had any effect upon the "minimum proportion" of the substance required to visibly alter the balance, and as one of the sources of resistance was the limited surfaces of the metals, I took plates of the two metals, each 3·5 centimetres wide, and immersed them 5·0 centimetres deep, and 1·0 centimetre apart in the water, and then balanced the potential of this cell through the ordinary galvanometer by that of the usual one with the smaller pieces of metal. On then adding chlorine to the water of the larger couple, the "minimum proportion" was found to lie between one part in 1,110,660,000 and 1,300,000,000, the same as with the ordinary couple. By other special trials of the same kind with hydrochloric acid and with potassium chlorate, the minimum proportions of substance required were found to be the same as when the usual sized pieces of metal were employed. From these results I conclude that the change of resistance due to change of size of metal had no conspicuous effect.

In each of the instances of measurement of energy of complex substances the amount of energy given is that of the true or definite "solution compound," not containing any excess of either ingredient. In order to ascertain the real combining proportion and formula of each complex substance, additional measurements were in every instance made, both of the amount of energy of the compound with an excess of one of its ingredients, and with an excess of the other (*see* Roy. Soc. *Proc.*, Vol. XLV., p. 265; also *Proc.* Birm. Philos. Soc., Vol. VI., Part 2; *Ibid.*, Vol. VII., Part 1, *Chemical News*, April 10, 1890). The true "solution compound" was in every instance indicated by a depression of voltaic energy, and the amount of energy in every case increased distinctly on adding a limited excess of either ingredient. The combining proportion indicated by the balance was in every case the same as the ordinary chemical equivalent. The list* includes about 324 of such compounds.

In the case of isometric solutions, caution must be exercised in accepting the numbers of one of each couple, the one having the largest amount of energy, because that one is usually unstable, liable to decompose, especially by elevation of temperature, and become converted into its isomer, with simultaneous loss of voltaic energy, KI+Cl (voltaic energy=2,045,138), and KCl+I (I=64,536) constitute an example (*see* Roy. Soc. *Proc.*, Vol. XLV., p. 440). $Na^2SO^4+2HNO^3$ and $2NaNo^3+H^2SO^4$ is another (see *Phil. Mag.*, October, 1889, p. 290).

The plus sign in the formulæ is used to separate the equivalent quantities. The amounts of voltaic energy are relative, not actual.

* The greater part of this list, owing to its length, has been omitted; it will, however, appear in full in the *Proc.* Birm. Philos. Soc.—ED. *E.*

188.	$KHSO^4$	16	18,298
189.	$K^2SO^4 + H^2SO^4$	17	18,016
192.	KI	19	16,361
196.	Ammonia alum	18	15,857
197.	AmCl	13·5	15,069
201.	$ZnSO^4$	22	13,654
216.	Oxalic acid	15	9,450
225.	KI + KCl	10	7,571
236.	NaCl + KCl	20	5,959
249.	K^2SO^4	12	2,274
253.	Na^2SO^4	13	2,020
291.	$MgSO^4$	20	216
295.	$CaCl^2$	16	181
365.	Water	16	0
366.	Alcohol (anhydrous)	15	−6·65
367.	Urea	19	13·6
374.	Cane sugar	15	67·8
378.	Carbolic acid (solid & colourless)	19	90·5
395.	Caffeine (perfectly white)	18	416
407.	Nicotine (brownish)	19	3,159
408.	Picric acid (variable)	17	3,585
417.	CaO	18	52,777
423.	Methylamine	19	241,019

The above order may be viewed as that of a volta tension series of liquids with a zinc platinum couple.

The influence of the kind of solvent upon the amount of voltaic energy is shown by the measurements made with chloride of calcium; this substance when dissolved in distilled water at 16°C. gave 181; in 7 volumes of glycerine and 3 of water at 18°C., 41·9; and in nearly anhydrous alcohol at 20°C., 23·4. A chemical analysis of the caustic soda employed, calculated for the anhydrous substance, gave 80·04 per cent. of NaHO and 19·96 of Na^2CO^3; and of the caustic potash, 77·6 KHO and 22·4 K^2CO^3. With a very pure sample, containing 97·64 per cent. KHO and 2·36 K^2CO^3, the amount of energy was −252,533. A sample of potassic cyanide, containing 92·11 per cent. of KCy, gave −148,737. It is interesting to notice that cane sugar acts as a dyad in uniting with common salt; the action, however, is not very distinct.

In this table the elementary halogens head the list; then follow the acids, acid salts, neutral salts, alkaline salts, and finally the alkalies, and complex compounds of alkaline reaction. Picric and carbolic acids are, however, amongst the substances yielding minus numbers. Strong solutions of carbolic acid, ammonia, or potassic cyanide (above 1 part KCy in 3,229 parts of water), when balanced by equal electromotive force, gave *plus* numbers.

The great decrease of electro-negative energy attending increasing complexity of chemical composition of the compound is strikingly shown by some of the mixtures employed, and is usually greater the nearer the aggregate of molecules approaches that of a mechanical mixture, and suggests the question whether the dissolved alkalies are usually composed of more complex molecules than the dissolved acids, which are nearly all of them near the other end of the scale.

By arranging well-known chemical groups of substances in series, with their amounts of voltaic energy, the latter forms, in various cases, a regular gradation of values; for instance, chlorine with potassic fluoride, chloride, bromide, and iodide; bromine with those salts; iodine with potassic chloride, bromide, and iodide; chlorine with sodic chloride, bromide, and iodide; also either potassic fluoride, chloride, bromide, nitrate, chlorate or iodate, with chlorine, bromine, and iodine; or sodic chloride with those elements.

The electromotive force of zinc in chlorine water, with platinum in solution of potash, the liquids being one-fourth saturated and separated by a parchment diaphragm, as determined by balancing it by the thermopile, was 1·2,644 volt. With platinum in each liquid it was ·944 volt, and with zinc in each liquid ·7,067 volt, the liquids in each case being at 18°C.

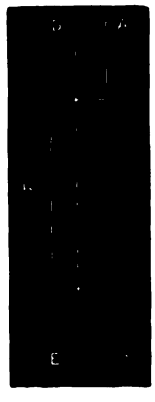
THE PHYSICAL SOCIETY.

At the meeting of this Society, on June 20th, Mr. C. V. Boys read a Paper

On the Measurement of Electro-Magnetic Radiation,

by himself and Messrs. A. E. Briscoe and W. Watson.

When Mr. Gregory described his new Electric Radiation Meter on November 1, 1889 (*The Electrician*, November 8, 1889, p. 16) one of the authors said that the observed effects might be due to some cause other than expansion by heating, and that if it was a true heating effect it might be measured thermally. The present communication describes experiments undertaken to investigate the question. The first method employed was developed from the idea that if two fine wires be placed near together and both act as resonators to a primary oscillator, the electro-dynamic attraction caused by the electric currents up and down the wires, and the electrostatic repulsion between the charges on them, might result in the relative motion of the two wires. From theoretical considerations, based on the assumption that the currents are harmonic in time and space, the authors inferred that the electro-dynamic effect would preponderate at the middle of the wires, whilst the electro static repulsion would be greatest at the ends. To cause the attractions and repulsions to conspire, cranked resonators A B C (*see* Figure) were



made; one was fixed and the other suspended by a quartz fibre, to turn about a middle line D E. These were enclosed in a glass vessel, and on starting the oscillator a turning movement was observed in a direction opposite to that expected. This motion was eventually traced to the electrostatic influence of the oscillator; for although the imperfectly conducting surface of the glass acted as a perfect screen from such action when the potentials of the oscillator were varied slowly, it did not do so for changes occurring about 500 million times per second. After adopting means to avoid this disturbance, and constructing lighter resonators, the experiments were repeated with negative results. From the dimension of the quartz-fibre used, it was estimated that a force of 158-millionth of a grain could have been detected with certainty. This would have corresponded to about $\frac{1}{300}$th of an ampere in each resonator. It is hoped that by further increasing the sensitiveness of the apparatus and using parabolic reflectors the effect sought for may be detected.

In the second method of attacking the subject, a Joule's dynamic air-thermometer was employed. This consisted of a glass tube, with a partition along the middle, extending nearly to the ends. If one side of the tube be warmed, convection currents circulate, and deflect an index placed in the stream. A small mirror suspended about one edge and counterpoised, was used for an index, and was so sensitive that it was impossible to get the air still enough by any ordinary method of screening. However, by the ingenious device of putting the thermometer within a larger tube kept rotating by clockwork, the difficulties were surmounted. A double wire, placed in one side of the thermometer, served as resonator, and on starting the oscillator a large deflection resulted. A similar deflection was caused by applying about $\frac{1}{3}$ of a volt to the ends of the wire. This proved that the effect observed by Mr. Gregory is due to heating. The least rate of heating observable with the air-thermometer was found to correspond to one calorie (gramme-water centigrade) per 24 hours in the whole tube, or one calorie per centimetre of wire in 103 days.

DISCUSSION.

Dr. LODGE asked Sir William Thomson whether, when electric pulses travel along parallel wires with the velocity of light, any action could exist between them, for two charged spheres travelling together at that velocity exerted no mutual attraction or repulsion.

In reply, Sir WILLIAM said he was inclined to think Mr. Boys' treatment of the subject was in the main correct; but it was quite possible that, at such velocities, the ordinary laws might be modified by the fact that the time taken for the force to be propagated from wire to wire was comparable with that required for the pulse to travel the whole length of the wire. As an example of the peculiar effects of rapid discharges, he said he had seen two copper wires which had been flattened against each other by lightning.

Mr. BOYS thought that in his resonators a condition analogous to stationary waves would exist, for the pulses were reflected from the ends.

Dr. LODGE said he had that afternoon observed the action of parallel strips when Leyden jar discharges were passed through them. The strips gave a kick at each discharge.

Mr. GREGORY mentioned that in trying to increase the sensitiveness of his meter so as to measure the variation with distance, he had found that two resonators in proximity interfered with each other. He had, however, succeeded in increasing the sensibility about five-fold.

Prof. WORTHINGTON asked if it was possible to measure the energy of the oscillator, and also whether the quantity caught by the resonator could be estimated from the solid angle it subtended at the source of energy, wherever that might be.

Prof. PERRY considered it easier to infer the energy of the source from that received by the resonator.

Dr. LODGE said the energy of the source could be easily measured. The power radiated was enormous whilst it lasted, vastly exceeding that of tropical sunshine; and if it could be made continuous, the apparatus would soon be red hot. The energy radiated, he said, converges on the resonators, and hence the solid-angle method of estimating the amount received would be erroneous. Moreover, the source was not at the oscillator, but at a quarter wave-length from it, and most of the energy returns to the oscillator; only a small fraction is splashed off and sent into space. Small oscillators radiate powerfully because the quarter wave-lengths are small, whereas the slow oscillators or alternators used commercially, radiate very little of their energy. The exact law of variation of intensity of radiation with distance was rather complicated, but the theory had been completely worked out by Stokes in 1848.

Mr. BLAKESLEY thought the energy that returns to the oscillator would be available for subsequent radiations.

Dr. LODGE pointed out that wires or other resonators placed within the quarter-wave-length would intercept part of the returning energy.

Two communications, "Notes on Secondary Batteries," by Dr. Gladstone and Mr. Hibbert, and "An Easy Rule for Calculating Approximately the Self-Induction of a Coil," by Prof. J. Perry, were taken as read.

In the first of these the authors show cause for believing that the beneficial effect produced by adding sodium sulphate to the ordinary electrolyte is due to its power to diminish local action between the electrolyte and different parts of the lead plates. As regards the chemical actions which take place during the working of ordinary cells, they see no reason to doubt the view put forward by one of them in 1882, that the substance produced in the voltaic reaction is ordinary lead sulphate, $PbSO_4$. They also conclude that the high E.M.F. of a cell immediately after stopping the charging current is due to the inequality of acid strength near the two plates, and the gradual fall of E.M.F. is caused by the equalisation of strength produced by diffusion.

Prof. Perry's rule relates to hollow cylindrical coils, and is expressed by the following formula:—

$$\text{L (in secohms)} = \frac{n^2 a^2 \div 10^7}{1{\cdot}844\,a + 3{\cdot}1\,c + 3{\cdot}5\,b},$$

where n = number of windings,
a = mean radius of winding in centimetres,
b = axial length,
c = radial depth of winding.

and b **and** c **are less than** $\frac{a}{2}$.

The time-constant of such a coil is given in terms of the volume of copper (V′) in cubic centimetres by

$$\frac{L}{R} = \frac{V' \div 1000}{\cdot 728\,a + 1{\cdot}33\,c + 1{\cdot}5\,b},$$

and the conditions for making this small are pointed out in the Paper.

Morgan's Electric Police Signal System.—A practical demonstration of this system is about to be made in the south-west of London; permission has already been obtained for the erection of thirteen signal lamp-posts, which will be connected by underground wires with the central depôt at one of the police stations. The apparatus is being made in Newhaven, Con., and operations will begin as soon as it arrives in England.

CENTRAL LONDON RAILWAY BILL.

HOUSE OF LORDS.—THURSDAY, June 19th.

On the motion for the second reading of the Central London Railway Bill,

The BISHOP of LONDON rose to move, as an amendment, that the Bill be read a second time that day six months. It was not usual, he said, for Bishops to oppose a railway Bill, but he was sure the indulgence of their lordships would be extended to him in this case on the ground that he considered the Bill involved danger to St. Paul's Cathedral. The proposal in the Bill was to carry a railway which would approach very near the Cathedral, and the station came within about 70 yards of the north-east corner of the Cathedral. Therefore it became a question of importance to consider what the effect would be on the stability of the Cathedral. From the records they had evidence that there was a considerable quantity of brick earth under the Cathedral, and under that sand and gravel, and lower down the London clay. Sand and gravel were water-bearing strata, and the fear was that the water might be drained away from the sand and gravel, which might sink. Considering the weight of the vast edifice it was feared there would be danger in any case. Moreover it was proposed to make a large station between the railway and St. Paul's, and it was obvious that the sinking of a shaft to the level of the railway in the construction of this station involved a serious risk. It was a noteworthy fact that the engineer in charge of this work was the same engineer who had charge of the London and Southwark Subway, and that subway was being constructed in the very manner in which this railway was proposed to be constructed. Well, the engineer stated in evidence in support of the Bill for the London and Southwark Subway that there would be no damage to the neighbouring houses; but he found that the subway had done mischief almost all along its extent. It was not a matter which ought to be decided on mere speculative evidence. Surely, if there was a doubt, they ought to give the benefit of the doubt to St. Paul's Cathedral. If any injury were to happen to that great fabric could a greater disgrace to the Parliament of this country be conceived than that they should have consented to bring very serious ruin upon one of the glories of the metropolis of England in order that people might be saved 15 minutes in coming from Bayswater to Cheapside? He appealed to their lordships to resist any speculation which might have such disastrous consequences.

VISCOUNT POWERSCOURT said he doubted very much whether any settlement of earth which might be caused at the distance of 250ft. from the Cathedral could affect the foundations of St. Paul's.

LORD SUDELEY thought that the motion was a most unusual one in regard to a Bill of this importance. Indeed, he believed it was almost without precedent, and he did not think a case had been made out. He would suggest that the Bill should receive a second reading, and then go to a Committee, where it could be thoroughly inquired into.

The EARL of MEATH said that when an attempt was made in the House of Commons to throw out the Bill on the report, its opponents did not go to a division.

VISCOUNT CRANBROOK suggested that they should let the Bill go to a Committee, and if the Committee were to make a special report whether, in their opinion, there would be danger to the Cathedral, and state their reasons, their lordships would have some grounds on which to proceed. At present they were acting in the dark, but if they had a report before them they could see whether the grounds were sufficient for proceeding with the Bill. If, on the other hand, the Committee came to the conclusion that there was no ground for going on with the measure, and that the preamble was not proved, of course the Bill would not come back to them at all.

EARL FORTESCUE thought it extremely undesirable, except in cases of the clearest principles, that either House of Parliament should attempt to discuss points of engineering or deal with matters which could only be satisfactorily settled before a Committee.

The BISHOP of LONDON said he should be glad to accept the advice of the noble viscount the Lord President, but he reserved to himself the right of opposing the further progress of the Bill, if it should appear to him that the decision of the Committee was not in accordance with the wisest course.

The amendment was then withdrawn, and the Bill was read a second time.

The time for petitioning in the House of Lords against the Central London Railway Bill has expired. From the petitions deposited, it is found that 19 petitioners will, unless previously settled with, appear in opposition to this Bill, which is just over half the number who lodged petitions in opposition when this Bill was before the House of Commons. Among the opponents are the Corporation of London, the Commissioners of Sewers, the London County Council, and the vestries of St. Marylebone and Paddington. The Railway Companies opposing are the Metropolitan and London, Chatham and Dover, whilst the remaining petitioners are landowners or others interested in property. Among these are the Dean and Chapter of St. Paul's, the owners and occupiers of property in Oxford-street, Cheapside, and Poultry, the Duke of Westminster, Viscount Portman, Sir James Bacon, Messrs. Trollope, the Paddington Estate Trustees, trustees of the late Duke of Portland, and the Ecclesiastical Commissioners.

Copper.—The prices of raw copper are steadily advancing, and stocks are being very considerably reduced, the visible supply showing a reduction of slightly over 6,000 tons from the 1st to the 15th inst. Chili bar quotations range at close upon £60

TELEGRAPH RATES TO AUSTRALASIA.

The following additional letters on the above subject from *The Times* of June 14th and 16th complete the correspondence, part of which appeared in our issue of 13th inst. :—

TO THE EDITOR OF "THE TIMES."

Sir,—In answer to Mr. Henniker Heaton's letter, which you publish to-day, I beg to state that he obtained possession of the Articles of Association of the Pacific Telegraph Company from my colleague in the matter, Mr. R. C. Want, under the pretext of obtaining Mr. Reid's signature, and signed them himself, in defiance of an assurance upon his part to Mr. Want that he would not do so. His signature was very nearly the occasion of the withdrawal of all my friends who had already signed, who fully share my conviction that any scheme with which Mr. Henniker Heaton's name may be associated is not likely to be favourably received in Australia. It may amuse Mr. Henniker Heaton to imagine that the bare fact of his signing the articles of the Company diffuses a talismanic glamour over its existence and smooths all obstacles in its path. I can assure him, from eight years' residence in Australia and four years' experience as secretary of the Company, that nothing of the kind is the case.

In the very laborious work undertaken and carried out by the Company in compiling statistics, in formulating proposals laid before the Colonial Conference, in establishing colonial agencies, in inducing Her Majesty's Government to survey the proposed cable's route—in all this Mr. Henniker Heaton, from the day of his signing the articles, has borne not the remotest share. He is quite content to let others work, while he appropriates as much of the credit as he can. I have only to add that, while Mr. Henniker Heaton became a shareholder in the Pacific Telegraph Company in the manner above set forth, he continues to be one only by the courtesy of the Directors, since he has never even paid for the one £10 share for which he subscribed.—I am, Sir, &c.,

HAROLD FINCH-HATTON, Secretary.

34, Clement's-lane, June 12th.

TO THE EDITOR OF "THE TIMES."

Sir,—I must compliment Mr. Harold Finch-Hatton on his plausibility and his dexterity. He now does not deny that I was the founder and originator of my Pacific Telegraph Company, and that he wilfully suppressed my name and the fact from the public that I had anything to do with the Company. The amalgamation with Mr. Want's Company, after that gentleman had returned from Australia, is also not noticed. The simple explanation of the new charge levelled against me is that Mr. Want and I agreed not to sign our names, but the gentlemen associated with me insisted on my signing, as I had induced them to go into the affair. Thereupon Mr. Want also signed. Mr. Harold Finch-Hatton says I did not contribute to the funds. He ought to have added the words "since Mr. Finch-Hatton became secretary." The fact is I have expended (as explained at the great public banquet given to me in the Town Hall, Sydney, on the occasion of my visit three years ago, at which the Mayor of the city presided, and for the first time the whole of the members of the present and late Governments met to do me honour) no less than £2,500 in advocating cheap postage and telegraphs to all parts of the Empire. But when I found that that expensive gentleman Mr. Finch-Hatton was taking a prominent part as secretary in our joint company, I declined to subscribe a farthing, and strongly dissuaded my friends from subscribing. With good intentions and many good qualities, he is not a financial genius ; and that a man in such a position certainly ought to be.—Very faithfully yours,

Carlton Club, June 14th. J. HENNIKER HEATON.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 13, 1890.

Gas Mains in New York. — Considerable excitement was caused the other day by an accident which shows the importance of immediate legislative action controlling the always more or less lawless gas companies. It is notorious that the gas mains in the lower part of New York City leak at innumerable joints, pouring out quantities of gas to permeate the earth with its noxious odours and accumulate wherever there is an opportunity to cause explosions. One of these many leaks chanced to be at the corner of Broadway and Fulton-street, one of the most crowded sections of the city, where an overturned lantern ignited the gas. The result was an immediate explosion in the subway beneath, seriously injuring one of the workmen, and then a column of flame shot up from the opening, gathering in volume as the intense heat started the neighbouring joints in the gas main. For 18 hours the flames poured into the air, threatening danger to passers-by, filling the adjacent buildings with noxious fumes and heating neighbouring electric conduits so as to completely cripple the service. After many hours of exertion the mains were blocked sufficiently to allow of smothering the flames. In certain portions of the lower part of New York these gas leaks have become so serious that a crowbar thrust into the earth and then withdrawn starts a stream of gas that may be only too readily ignited. There seems to be a singular carelessness on the part of the authorities in allowing such leaks to exist. If the electric light companies were to show symptoms even of the same amount of carelessness they would have to go out of business ; but the public does not seem to realise that while a poor electric conduit only damages the company, a leaky gas main is a continual peril to life and property in the vicinity.

Electrical Execution.—The case of Kemmler, condemned to die by electricity, is again called to public attention from the fact that Judge Wallace has just vacated the writ of *habeas corpus* which delayed the execution appointed for last May. The general opinion seems to be that he will be executed in the early summer by the means prescribed by law.

The Direct Conversion of Heat into Electricity.—The country papers just now are full of reports of a method of converting heat directly into electricity, said to have been invented by a young man who hails from the State of Maine. The reports are mainly remarkable in their omission of all details that might lead to any possible information concerning the process, and it is altogether probable that this is only one of the numerous *canards* that float around in quasi-electrical circles.

The Prospects of Electric Traction in New York.—Governor Hill's non-signature of the Cable Bill gives New Yorkers one more chance to have genuine rapid transit, provided that the Manhattan Elevated Railway magnates do not succeed in smothering any attempts made in this direction. There is an admirable opportunity for a four-track underground system, reaching the entire length of Manhattan Island, and nothing short of it will ever relieve the city from the pressure to which it is now subjected. There is great talk of an enterprise of this sort being inaugurated shortly ; but there are plenty of political stumbling blocks in the way of success of such a plan, and it is much to be feared that its day is not yet.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *June* 20, 1890.

The use of electricity for lighting is really beginning to increase very materially in Scandinavia ; more in Sweden, I think, than in Denmark and Norway, although in these countries, too, people are commencing to go ahead in this respect. In the first-mentioned country several small towns have adopted electric lighting for the streets, *i.e.*, Hernösand and Östersund ; and others have decided upon it, among them being Helsingborg and Sundsvale, where the installation is in course of erection. Siemens and Halske, Berlin, have secured the contract for the Helsingborg installation. In this town underground cables will be adopted for the more central parts of the town—the first instance in Sweden, I believe, of underground cables for lighting of a town. The Stockholm Gas Works have recently purchased some well-situated property at a price of 360,000kr. for the purpose of turning it into a central electric station, which will be proceeded with without delay.

In Copenhagen the Corporation has also bought some property in the centre of the town for their central station. In this town electric lighting appears to be coming very much to the fore ; and the applications to the Corporation for electric light installations have been so numerous that an extension of the originally contemplated plan will, no doubt, be necessary. Danish electrical engineers are now very busily engaged in securing the orders for fittings, &c. In Gothenburg the town has just refused an offer from the private lighting Company to sell their installation ; but in other towns the civic authorities do not seem disinclined to take up the matter of electric lighting on their own account. Several Norwegian towns, including Christiania and Skien, will adopt electric lighting on a larger scale. The Elektrisk Bureau of Christiania, which has already completed a very large number of installations, have secured the contract for the installation at Gaustod Lunatic Asylum. This will consist of machine-power for 520 and accumulator battery for 200 incandescent lamps of 16 candle-power. This year about 500 lamps of 10, 16, and 32 candle-power will be installed in the various

Digitized by Google

buildings belonging to the asylum itself, and later on the installation will be extended to the out-buildings.

In Sweden a large number of electric installations in industrial establishments have been completed of late, prominent among which are a good many sawmills. Whenever new industrial works are erected, or extensions of old ones made, it is almost a matter of course that electric light is adopted.

If electric lighting can be said to have made satisfactory progress, everybody must admit that the telephones are making a marvellous advance. In no country in the world, I fancy, has the telephone come into more general use than in Sweden. People who in England would not dream of having what they would consider a luxury, would in Sweden little think of doing without; it has there almost become a necessity. The Stockholm General Telephone Company is a model institution, to which I have had occasion to refer in previous letters. Their report for last year contains several items of interest. It appears that co-operation has been secured with the telephone companies in the towns of Upsala, Vesterås, Norrköping, and Nyköping; and further arrangements of co-operation also with the State telegraphs and telephones are pending. During 1889 the Company installed 825 telephone connections for new subscribers in Stockholm, and 195 subscribers have, for various reasons, given up the telephone. The total number of subscribers was at the beginning of the year 4,556, and at the close 5,186. There were direct lines, 2,820; telephone with two-line automatic exchanges, 514; telephone with five-line automatic exchanges, 949; lines at country stations, 216, &c. In addition to these, 22 telephones are in connection with the Company through the police telephone station, and 54 through the State telegraphs. The total number of conversations during the year amounted to 10,535,056, averaging 32,312 conversations per day, and 6·71 conversations per subscriber per diem. The number of telephone clerks employed was at the end of the year 98. The length of wire in the Company's connections was 9,790 kilometres. The total number of hands employed was at the end of the year 173. In addition to the Stockholm business the Company has at Söderhamn an installation with 342 subscribers, and at Jönköping one with 144 subscribers, both of which have shown material increase during last year. The net profits of last year's working amounted to 64,780kr. (1kr. = 1s.) The shareholders get an 8 per cent. dividend, and 15,000kr. are added to the reserve fund, and smaller sums added to various other funds.

Negotiations have for some time been pending between the Stockholm Corporation, the State telegraphs, and the Telephone Company about carrying underground telephone cables through the streets. Co-operation will also be arranged between the State telegraphs and the two telephone companies; but the question has been a difficult one to settle on account of the various conflicting interests.

The first electric locomotive in Sweden has recently been imported from New York by the Wenström and Granström Electric Power Company at Arboga; it is intended for the Boxholm Electric Railway.

THE PLYMOUTH SHOW.

The fifty-first country show of the Royal Agricultural Society of England has been held during the current week at Plymouth. As in previous years, we have to record an almost total absence of electrical machinery and exhibits; although from the fact that a few exhibitors put electrical manufactures amongst their exhibits evidence is not wanting that some day the Council of the Society will rise to the occasion, and make an effort to prove to the large numbers who visit the Show that it is possible for agriculturists, equally with other sections of the community, to utilise electrical machines and to take advantage of discoveries and inventions which are now so freely used by all classes. Amongst the exhibits at Messrs. J. Armfield and Co.'s Stand are a 5-unit and a 3-unit self-regulating dynamo, and a ¼ horse-power electric motor, all made by Mr. Veale, of St. Austell, Cornwall, and exhibited specially to show their adaptability for driving dairy and farm machinery; and Messrs. Priestman's show includes a complete electric lighting plant, comprising 30-light dynamo, 34 accumulators, together with all the necessary fittings, cables, switches, &c., and a ¾ horse-power electric motor, the whole manufactured by Mr. F. M. Newton, of Barton Grange, Taunton.

Messrs. John Fowler and Co. (Limited), of Leeds, show a 12 horse-power horizontal compound engine, fitted with automatic expansion gear on both cylinders, controlled by one governor, and specially constructed for electric lighting and where steady running is essential. Messrs. Robey and Co. show, amongst a number of engines exhibited, a high-speed vertical engine, specially suited for small electric light installations, ship lighting, &c., the engine having a working pressure of 80lb. Messrs. Francis Morton and Co. (Limited) have a fine display of their well-known manufactures. Messrs. Ransomes, Sims and Jefferies, in an exhibit consisting of 42 items, show a 10 horse-power compound "Undertype" engine, with patent automatic governor expansion gear, constructed specially for driving electric light machinery.

Messrs. Davey, Paxman and Co. exhibit two steam engines of the portable type, which have been selected by the jurors of the Show to drive the various machines sent for competition. One is an 8 horse-power compound engine, and the other an 8 horse-power single cylinder engine. Messrs. Davey, Paxman and Co.'s great experience in the manufacture of compound steam engines has again received recognition in the selection of their engines by the jurors, as above mentioned. It is one of the firm's contentions that first-rate results can be obtained with compound engines working without condensers; and the performance of the compound engine now under consideration certainly goes to verify their statements on the subject. The pattern and construction of the engine are especially worth careful observation. It is complete in itself, being built on a steel channel frame, bolted to a bracket on the boiler. By removing a few bolts the engine and frame can be lifted from the boiler, and fixed and worked separately. This design undoubtedly displays many features of considerable interest and merit. Both engines are fitted with Paxman's automatic gear, which is well known for its simplicity and effectiveness in controlling engines used for the electric light at the various exhibitions where Messrs. Davey, Paxman and Co. have had so many installations under their control. This firm also exhibit a 16 horse-power "Undertype" engine, and a girder engine, large numbers of the former of which are turned out by the firm every year. Another feature of this firm's exhibit is the latest patent vertical boiler, called the "Essex," to which they have devoted much attention, with the result that they have succeeded in designing and making a thoroughly economic vertical boiler. The construction of the boiler is noticeable; and to render explanation simple, Messrs. Davey, Paxman and Co. show the tube division of the boiler, from which it can be seen that the tubes pass from a wedge-shaped chamber on one side of the boiler to a similar chamber on the other. These are curved to a radius somewhat greater than that of the boiler. A neck connects one of these chambers with the firebox, and to the other one is attached the funnel. They are both provided with a door, so that the tubes can be cleaned or replaced with facility. The shape of the flues causes a centrifugal action in the hot gases, which brings each portion into direct contact with the tube surface, so that the highest efficiency is obtained from the heating surface, while at the same time good circulation of the water is secured.

Messrs. Marshall, Sons, and Co., have on view a 6-horse power portable steam engine, constructed for a working pressure of 80lb.; and a compound stationary steam engine of 12-horse power, placed under a boiler of the locomotive type, with patent automatic expansion-valve gear, and sight-feed lubricator to high-pressure cylinder. Mr. E. S. Hindley shows a 3 horse-power vertical engine combined with a vertical tube boiler, for 60lb. pressure to the square inch; and an 8 horse-power horizontal engine on cast-iron foundation, the cylinder lagged with mahogany and brass bands. Messrs. Brown and May have on view a Knight's patent portable paraffin engine of 1 horse-power nominal, for which they claim that any mineral oil can be used, and only one sort of oil need be kept by the purchaser. This firm also exhibit, amongst other engines, a 10 horse-power horizontal steam-engine, which is self-contained, and especially designed to work at its maximum power.

Messrs. Priestman Brothers (Limited) show a 11 horse-power Priestman's patent portable oil engine, mounted on wheels, with shafts, which drive one of Wallis and Steevens' threshing machines, for which purpose it appears to be very suitable; a 5 horse-power Priestman's patent portable oil engine, mounted on wheels, with shafts, &c.; and a 2 horse-power Priestman's patent horizontal oil engine, shown in connection with the electric lighting plant mentioned above. The makers inform us that they are busily employed with home and foreign orders for this latter type of engine.

Messrs. Crossley Brothers (Limited) have a fine exhibit of gas engines, including a new design high-speed electric light engine known as D size, which is specially arranged to run at 250 revolutions and to give seven revolutions on the pulley. The firm guarantee absolute steadiness for this engine, which drives direct on the dynamo, and they claim that it is unnecessary to attach to the dynamo a fly-wheel or disc, as is usually the practice. In addition to this special electric light engine, the firm show three horizontal "Otto" engines, and a gas engine and pump combined, an advantage connected with the latter being that when the pump is not in action the engine can be used for other purposes. Gas engines are also exhibited by Messrs. T. B. Barker and Co., who show a 7 horse-power and a 2 horse-power "Forward" engine, the latter of the new "Undertype" pattern, with automatic hot tube igniter; and by Messrs. Fielding and Platt, who have on view a 4-horse power and a 1-horse power "Fielding" gas engine, for

Digitized by Google

which they claim advantages over many other engines in the market.

In addition to the exhibits mentioned above, which are chiefly situated in the department for machinery in motion, there are some excellent shows of lubricants and cylinder oils, belting, scientific instruments for food-testing purposes, the useful manufactures of the Sanitas Company, and some specimens of wood engraving, zincography, Nature-process work, and electrotyping, by Messrs. Dawson, Wilmer, and Clift.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—It will be seen by our advertisement columns that the Town Council of Winchester are prepared to consider tenders for the lighting of the streets of the City and Corporation buildings by electricity. Full particulars and conditions can be obtained at the town clerk's office, and tenders are to be sent to Mr. Walter Bailey, town clerk, on or before 1st September next.

——— The Local Board for the District of Carshalton invite tenders for the lighting of the district with gas, oil, or other illuminant, at per lamp, exclusive of the cost of columns, frames, and lanterns, for a period of twelve months from July 31st. Tenders, endorsed "Public Lighting," and addressed to the Chairman of the Board, are to be deposited at the Board Offices, High-street, Carshalton, by 12 o'clock noon on Wednesday, July 9th.

——— The General Direction of Posts and Telegraphs in Madrid will receive, up to Thursday, July 10th, tenders for the installation and maintenance of a telephone exchange at Linares, Prov. Jaen, Spain.

TECHNICAL JOURNALISM.—We have received from a gentleman occupying a leading position in the electrical world some interesting particulars of an application recently made to him by a journal claiming to have an enormous *clientèle* amongst railway companies, contractors, &c., &c., asking to be favoured with a description of a leading line of his manufactures, which the editor of the journal in question would be pleased to insert, subject to our correspondent's approval of the proof, on the condition that reprints of the article were supplied or that the article should afterwards appear as an advertisement in the said journal. Our correspondent further says that the specimen sent us is only one of a pile of letters he is constantly receiving from the same source. We regret that we are unable to do more than call attention to the matter in this indirect way, as, so far as we can see, the journal in question cannot legally be prevented from adopting this method of securing notice from circles which it would not otherwise reach. Our correspondent may derive consolation from the fact that he is by no manner of means the only victim of this system of touting. He can further rest assured that the journal which has thus importuned him is not a representative one, but is one which, even in London, is but little known and less respected.

THE TECHNICAL AND GENERAL NEWS AGENCY.—This agency has been formed to supply cuttings from English and foreign technical and trade papers, for the use of the press and electrical and engineering firms. The temporary offices are situated at 46, Cranmer-road, Brixton, S.W.

PARTNERSHIP DISSOLVED.—The Morgan Crucible Company, of Battersea, crucible manufacturers, has dissolved partnership, the business being transferred to a limited liability company.

THE WATKIN TOWER.—Some misapprehension exists as to the arrangements which have been made in connection with the proposed high tower for London. Although the prizes have been awarded nothing definite has yet been fixed as to the design which will be ultimately adopted, nor as to the site to be selected.

A NEW PRIMARY BATTERY FOR SURGEONS.—We have received particulars from Mr. Henderson, of Brazenose-street, Manchester, respecting his new primary battery, for which he claims simplicity and excellence of construction. The main details are such as are usual in batteries of this class—zinc-carbon elements in a solution of bichromate of soda and sulphuric acid; but an important feature is the arrangement of the connections, which are such as to allow of the six cells being arranged either in series (12 volts) for lighting purposes, or in mutliple series (6 volts) for cautery and other surgical operations. The current is 25 amperes per cell, and the battery is put in or out of action by a foot-lever. Care has been especially taken in the method adopted for attaching the carbons; the metal lugs are heavy, and after attachment the carbons are soaked in boiling paraffin and coated with a new impervious varnish two inches down. The zincs are cut from best rolled zinc. There is a simple rheostat attachment for regulating the current for lighting instruments. There are no loose parts, and the battery forms a neat box; and doctors, dentists, and others, will find it a very useful and cheap source of electrical energy.

MESSRS. CUTTRISS AND CO.—We have received from Messrs. Cuttriss and Co. their new catalogue of dynamos, motors, and electrical appliances. Attention is called to the fact that the firm have recently taken much larger premises at Elmwood Electrical Works, Leeds. Illustrated particulars are given of a students' dynamo, manufactured for lecturing purposes, of which Messrs. Cuttriss have made a large number; of the Eclipse dynamo, of the Ring dynamo and motor; of the Alliance dynamos and motors; and of the Dental motor, designed to meet the requirements of the dental profession. An illustration is also given of a cheap motor and ventilating fan manufactured by Messrs. Cuttriss, and of a low-resistance six-cell battery, made in two sizes, one of three pints and one of ten pints capacity. The catalogue closes with a description of the Cuttriss calculating disc, described in *The Electrician* of June 6th, p. 109.

THE AUTOMATIC ELECTRIC RAILWAY COMPANY (LIMITED).—The liquidator of this Company invites offers for the various patents belonging to the Company for the United Kingdom and the Isle of Man. The advertisement states that the inventions have been tested on the Pennsylvania Railway, the New York Central Railway, and the Dortmund Gronau Enschede Railway, with satisfactory results. The liquidator, from whom all further particulars can be obtained, is Mr. J. Harvey Evans, 11, Rumbold street, Liverpool.

ROYAL MILITARY TOURNAMENT.—A very successful installation of the electric light has been put down at the Agricultural Hall, by the Acme Electric Works, from power supplied by Griffin gas engines.

FLY CYCLE COMPANY (LIMITED) (IN VOLUNTARY LIQUIDATION).—We have received a note from the liquidator of this Company, Mr. F. G. Emms, of 4, Bethel-street, Norwich, showing the liabilities of the firm to be £3,783. 12s. 7d., against assets estimated to produce £2,728, leaving a deficiency of £1,055. 12s. 7d.

COMPANIES' MEETINGS & REPORTS.

West African Telegraph Company (Limited).

Report of the Directors to the fifth ordinary general meeting, to be held at Winchester House, Old Broad Street, London, E.C., on July 3rd, 1890, at twelve noon :—

The Directors submit the accounts and balance-sheet of the Company for the 12 months ended December 31, 1889.

The Company's revenue for that period amounted to £64,661. 1s. 1d., against which £21,155. 9s. 8d. is charged for ordinary expenses, £1,780. 3s.1d. for hire of cable-repairing ships, and £509. 16s. 2d. for income-tax, leaving a balance of £40,465. 12s. 2d. which, with £4,878. 4s. 8d. brought forward from the preceding year, makes a total of £45,343. 16s. 10d. From this amount is deducted £17,643. 15s. 10d., being for interest on debentures £14,477. 2s. 6d. and for sinking fund £3,166. 13s. 4d., leaving a balance of £27,700. 1s., out of which the Directors have placed £16,145s. 11s. to a general reserve fund.

The Shareholders have received for the six months ending 30th June, 1889, an interim payment amounting to 3s. 6d. per share, and the Directors now recommend a dividend of 6s. 6d. per share, making up 5 per cent. free of income-tax for the year ended 31st December, 1889, which, with the appropriation to the general reserve fund of £16,145. 11s., will absorb the balance standing to the credit of the revenue account.

The Directors have, in addition to the amount of £16,145. 11s., taken from this year's revenue account, placed the balance of £3,074. 2s. 5d., which was standing on the repairs and renewals account, to the general reserve fund. With the interest received during the year from investments, £493. 4s. 7d., this fund now amounts to £19,712. 18s.

The cable between Bonny and Prince's Island (Principé), referred to in the last report, appears as an addition to the capital expenditure during the year. The expenditure on capital account has been increased by £24,771. 7s. 9d. to £508,900. 16s. 5d.

The traffic under the friendly arrangement between the companies whose systems virtually surround the African coast has grown much to the advantage of this Company. The working of these lines as an alternative route has given not only security to the telegraphic system on both the East and West coasts of Africa, but has also largely benefited the revenue of this Company.

The cables of the Company continue in good working order.

The Directors who retire by rotation are Sir John Pender and Robert Kaye Gray, Esq., who, being eligible, offer themselves for re-election.

Mr. James Pender having resigned his seat at the Board the Board have nominated Mr. John Denison Pender Director in his stead. The meeting will be asked to confirm the appointment.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., offer themselves for re-election.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons of the Company's Four per Cent. Mortgage Debentures due July 1st next will be paid on and after that date at the Alliance Bank, Bartholomew-lane, London, E.C. The coupons must be left at the bank three clear days for examination. Warrants for the payment of interest on the registered debentures will be sent out on the 30th inst. The debenture register will be closed from the 27th to the 30th inst., both days inclusive.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—Notice is given that Coupon No. 5 of the Six per Cent. Debentures of this Company will be paid, less income-tax, by the Alliance Bank, Bartholomew-lane, on and after July 1st.

BEALE'S (LIMITED).—A Company under this style and title has been incorporated, with a capital of £75,000, in shares of £1 each. The Company is established to carry on the following businesses :—Public caterers, restaurateurs, bakers, confectioners, retail cake and biscuit manufacturers, general provision dealers, licensed victuallers, and electric light and power contractors. We recently announced the formation of a Laundry and Electric Light Company. Whatever may be said against the electric light, it cannot be said that it does not lend itself to commercial combination.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's second issue of Five per Cent. Debentures, due 30th inst., will be paid on and after that date, at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the bank three clear days for examination. The receipts of this Company for the week ended June 20th, amounted to £4,098.

COLUMN PRINTING TELEGRAPH INSTRUMENTS.—During the past week advertisements have appeared in some of the financial papers with reference to the instruments recently advertised by the Column Printing Telegraph Company, in the course of which a challenge has been thrown out to the Exchange Telegraph Company to submit their instruments to some kind of promiscuous test. To this the latter Company reply that the challenge in no way disconcerts them, the concluding paragraph of their rejoinder being as follows : "We have said what we consider necessary on the subject of the Column Printing Telegraph Company's prospectus, and await the result. We would state that we have said nothing on the subject of the Column Printing Telegraph Company's prospectus but what we are prepared to substantiate ; and it is not likely, with the threatened litigation, that we should accept a trial of instruments where we may yet have to deal with a case of patent infringement."

LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE.—The Directors of this syndicate have decided to recommend to the shareholders, at a meeting to be held on July 18th next, the declaration of a dividend at the rate of 5 per cent. per annum for the period ending March 31st last. The balance sheet of the Company shows a profit at a rate of nearly 9 per cent. per annum, out of which a considerable sum will be carried to reserve.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY.—Messrs. Robert A. McLean and Co., 1, Queen Victoria-street, London, E.C., notify that the half-yearly interest on the First Mortgage Bonds will be paid on July 1st. Coupons must be left three clear days for examination.

THE RECOVERY OF METALS BY ELECTRICITY.—We understand that a project will shortly be placed before the public for subscription for the electrical recovery of pure tin from scrap. We have seen the reports of experts, which are of the most encouraging character ; and with the very considerable and growing demand for this metal no difficulty should be experienced in successfully launching the Company.

STOCK EXCHANGE.—The Committee have appointed Tuesday, July 1st, a special settling day in the Notting Hill Electric Lighting Company (Limited)—ordinary shares, Nos. 142 to 6,459 ; and have ordered the under-mentioned security to be quoted in the official list : Western and Brazilian Telegraph Company (Limited)--further issue of 419 shares, Nos. 91,559 to 92,047. Application has been made to the Committee to appoint a special settling day in the Commercial Cable Company, £2,716,000 capital stock.

SUBMARINE CABLES FOR THE FRENCH COLONIES.—The Paris correspondent of *The Statist* announces that there will shortly be formed a new Submarine Telegraph Company, whose business will be to lay cables connecting the French Colonies with other countries. The prospectus was issued on Wednesday last for 11,000 shares of 500fr. each, at par, under the auspices of the Comptoir National, Société Générale des Téléphones, Banque d'Escompte, &c. The Company obtains from the French Colonies an annual subsidy of 260,000fr. and from the Dutch Colony of Curaçao the guaranteed annual minimum receipt of 95,000fr. The Paris Telephone Company guarantees to the shareholders of the new Company 5 per cent. annual interest.

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—Notice is given that Coupon No. 11 of the Five per Cent. Debentures of this Company will be paid, less income-tax, by Messrs. Martin and Co., 68, Lombard-street, on and after July 1st.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended June 20, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,154.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

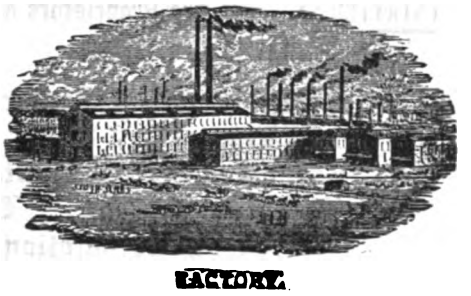
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50th. to 1in.



FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

JABLOCHKOFF'S DISTRIBUTION PATENT

(BEING A PATENT FOR "PRODUCING AND DIVIDING ELECTRIC LIGHT," No. 1996 of 1877.)

THE ELECTRICAL ENGINEERING CORPORATION, LIMITED

(STATTER'S) **Are Proprietors of the above Patent, and Warn the Public against Infringement.** (UNITED).

The following are Licensees:—

Brush Electrical Engineering Company, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.

3, PRINCE'S MANSIONS, VICTORIA STREET, WESTMINSTER. PERCY E. SCRUTTON, *Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 633.—Vol. XXV. FRIDAY, JULY 4, 1890. Price Fourpence.

NOTES.

There were three men who led the way in electric lighting by glow lamps. One of these was Mr. Lane Fox, nor was he the least original or persevering or scientific of the three. But we regret, and the regret will, we are sure, be shared by all fair-minded people, that he has received the least reward for his work. We understand that one of the transfers alluded to by the Chairman at the recent meeting was a sale of the patents by the inventor, but we have not endeavoured to push our investigations into this matter. That very great credit is due to Mr. Lane Fox cannot for a moment be denied; but that royalties are also due is, unfortunately, a matter of uncertainty, that is to say, a matter of law.

The meeting which was held on Tuesday was too small to be of any value as a representation of the trade, but was important as the occasion of a clear statement by the Lane Fox Electrical Company of their claims, and, to a certain extent, of their attitude. If the royalty which they claim from the Kensington and Knightsbridge Company really only amounts to £300 a year for two years, the matter is hardly worth discussing, and certainly not worth fighting about. The exact sum concerns no one but the negotiating parties; but if the undertakers find it to be a burden, they would be put to but little inconvenience if they disconnected their batteries and kept up steam, running their engines at times on a very light or on a very heavy load, and until the patents expire. The cost of coal and attendance would be easy for them to calculate. Then arises the question of retrospective royalties; and here, as a matter of common fairness, the Lane Fox Company must, before they ask for royalties, explain clearly, and, if necessary, subject to discussion, why so few attempts have been made to uphold the patent. We understand that the "Pavilion" case and the "Athenæum Club" case, were both founded on this patent, but we are speaking from hearsay, as the history of electric lighting has yet to be written; and a very interesting history it will be. At all events, no case was ever won on this patent, and the argument has been used more than once, that the Anglo-American Brush Company can hardly be credited with purely philanthropic motives for the way in which, while holding this patent, they have allowed the use of accumulators for lighting purposes without a murmur.

It is somewhat difficult to account for the summary rejection last week of the London Overhead Wires Bill. If the metropolis is to be saved from a modified repetition of the recent mishaps in New York, the overhead wire question should be placed on a satisfactory basis; and reasonable regulation by the County Council would appear to be the best solution. The Bill in question provided such reasonable regulation; but the fact that it contained a clause giving powers of compulsorily entering upon private property for the purpose of putting up wires and inspecting them proved sufficient to ensure its rejection, although endeavours were made to guard the rights of householders. One member, not acquainted apparently with the model form of Provisional Order, said the question was not one of erecting telephone wires but electric light wires. But, as Sir J. Bailey pointed out, it is the derelict wires which are most in need of supervision, the "live" overhead wires in the Metropolis, whether for electric lighting or telephonic purposes, being probably as safe as any in existence. We trust another attempt will be made next Session to devise a Bill which will attain the objects of the one just thrown out, without arousing such strenuous opposition on the part of owners of property.

The numerous questions which have been asked in the House of Commons with regard to the transfer clauses which the Board of Trade has thought fit to insert in the Provisional Orders granted to Local Authorities show that this new departure is not viewed with unqualified satisfaction by members of the Legislature. Up to the present members have only received the stereotyped reply given to the recent deputation of electric lighting companies. The President of the Board of Trade has "confidence in the discretion of the Local Authorities." However well this confidence in the discretion of Local Authorities may be justified, it would nevertheless be satisfactory to learn in what way electricity differs so greatly from gas that the introduction of the foreign principle of "concessions" has been rendered necessary.

We publish this week an interesting note on the magnetic circuit by Mr. Carter, who has also worked out a useful table of constants, by aid of which calculations connected with the design of dynamos may be shortened. The analogy between electricity and magnetism is complete in every respect when properly worked out in the way Mr. Oliver Heaviside has shown; and a Paper setting forth this analogy in simple language would serve a very useful purpose. Mr. Carter has, however, not chosen the right analogue of electric resistance. The analogue of lines of induction produced by magnetic force is really the charge of a condenser produced by electro-

Digitized by Google

motive force. The electric resistance determines the waste of energy caused by the passage of a current, but the quantity often called magnetic resistance is not in any way associated with waste by heating, and is really analogous with capacity. No substance has yet been found to conduct a magnetic current in the way a piece of copper conducts an electric current, or the true analogue of electric resistance would be well understood. It is true, as Mr. CARTER says, that unnecessary complication arises in calculations from the mixture of metrical and English units; and it is, therefore, to be regretted that in working out the table of numbers the foot has been taken as the unit of length and the square inch as the unit of area.

ON the 1st of July, 1894, the existing agreement between the Glasgow Tramway and Omnibus Co. and the Glasgow Corporation, for the working of the municipal tramway system of that town, will expire; and the question of what is then to be done has already been raised. Negotiations have been entered into with present lessees, but so far it has been impossible to arrange mutually satisfactory terms. The Corporation have therefore now to consider whether they will get a special Act and work the tramways themselves, lease them to another Company, or enter into further negotiations with the present one. Many members of the Corporation, we believe, advocate the working of the lines by the municipal authorities themselves, and the adoption of electricity.

THE Glasgow Corporation, it will be remembered, is at the present moment promoting an electric lighting Provisional Order, and proposes to expend a large sum of money in establishing an electricity supply system. Should the municipality therefore decide to obtain a special Act we trust there will be a clause permitting the use of electric traction, which it will be able to adopt under especially favourable circumstances. Inquiries, we are told, have been already set on foot with a view of obtaining reliable information upon the subject of electric traction. We would suggest to the Corporation that instead of confining these inquiries to what is being done in this country, and remaining content to witness experimental runs of experimental cars, that they should engage the services of a competent electrical engineer, and should instruct him to place before them reliable statistics relating to the total mileage, cost of working, and different systems of the electrical street railways of the United States. A Corporation owning tramway lines 30 miles in extent, and upon which it has expended about £350,000, would do well to be in possession of all the facts relating to electric traction before deciding as to its adoption or rejection.

THE prospectus of the International Okonite Company, which was issued early this week, has been so drawn up as to avoid all technical criticism. Not the smallest hint is given as to what okonite is; the nature and extent of the sources from which it is obtained; the price, which we understand is about three times that of gutta percha; or the materials with which it competes. Neither the result of laboratory tests, nor the testimonials of those who have used it in practice, can be taken as a guide to an investor in a manufacturing business of this kind. The main question is, how will it compete with the thoroughly reliable products of the old-established firms of this country?

WE are glad to hear that there is every probability that the £3,000 which is required to enable the Maxim-Weston Company to continue its operations will be subscribed among the shareholders.

OUR readers will be glad to see that we are commencing in the present issue the second series of articles by Dr. FLEMING. These will constitute the second volume of "The Alternate-Current Transformer in Theory and Practice," and will be devoted to the applications of theory to practice, including the subjects of Measurements, the Construction, Design, and Use of Transformers, and their applications in lighting, welding, and other work.

The Halifax-Bermuda Submarine Cable.—The laying of this cable has been completed.

"Electrical Plant."—We are informed that Mr. E. R. Dolby is now editing *Electrical Plant*.

King's College.—The Professorship of Mechanical Engineering at this College will shortly be vacant.

Personal.—Mr. A. E. Mavor has been appointed general manager of the Fowler-Waring Cables Company.

Royal Institution.—The general monthly meeting of this Institution will be held on Monday, July 7th, at 5 p.m.

Electric Lighting Acts Amendment (Scotland) Bill.—This Bill was read a third time in the House of Lords on Tuesday last.

City of London and Southwark Subway Bill.—This Bill was read a third time in the House of Lords on Friday last and passed.

Newry.—The Irish House-to-House Electricity Company has announced its intention of applying for a Provisional Order for Newry in the next Session of Parliament.

Postal Telegraph Revenue.—The receipts from the telegraph service for the quarter ended June 30, 1890, amounted to £555,000, as against £525,000 for the corresponding quarter last year.

Society of Arts.—At the meeting of the Council of this Society on Tuesday last Sir Richard Webster was elected chairman and Sir Frederick Bramwell deputy-chairman for the ensuing year.

Telegraphic Communication with Tory Island.—The steamer Buccaneer left Silvertown on Wednesday to lay the cable connecting Lloyd's signal and telegraph station on Tory Island with the mainland.

Merchant Venturers' School, Bristol.—The posts of Physical and Mathematical and of Chemical and Metallurgical Master at this school are vacant. Further particulars will be found in our advertisement columns.

Personal.—Mr. F. Quicke, works manager to Messrs. Immisch and Co., was installed Worshipful Master of the Chislehurst Lodge of Freemasons, No. 1,531, at Chislehurst, on Saturday last, in the presence of a large number of metropolitan brethren.

Personal.—We are informed that Mr. William Robinson, M.E., Senior Demonstrator of Physics and Electrical Engineering at Finsbury Technical College, was yesterday unanimously appointed Professor of Engineering at University College, Nottingham.

Leeds.—Owing to the gas stokers' strike, the *Yorkshire Post* had to be produced by candle-light, but on Wednesday the electric light was temporarily installed at the offices of that paper. At the *Leeds Mercury* offices the electric light has been in use for some time.

Digitized by Google

Coventry.—The Coventry Telephone Exchange was opened on the 24th June last year with 27 subscribers; there are now 90 subscribers. In the first week there were 32 "trunk" calls and 748 local; the record for the last week of June shows 287 "trunk" calls and 2,930 local.

Liverpool Engineering Society.—The first excursion this season of the above society was to Keswick. A visit was made to the works of the Keswick Electric Supply Company. A representative of Messrs. Fawcus and Cowen, the engineers for the scheme, explained the working of the system.

The Electric Light in Holland.—The Communal Council in Amsterdam is now discussing the proposal for granting an exclusive concession for the electric lighting of the city during a term of years. The town authorities of Rotterdam have also introduced a similar Bill into their own Council for the lighting of Rotterdam.

Electrical Trades Section River Excursion.—This excursion will take place to-morrow. The "Viscountess Bury" will leave Windsor at noon, and is expected to reach Henley at about six p.m., and the party will return from Henley by train. It is expected that arrangements will be made with the Great Western Railway for special facilities.

Telegraphic Communication between France and the North African Coast.—M. de Selves has submitted a report to M. Jules Roche, the Minister of Commerce, asking for two new cables to be laid connecting Marseilles with Oran and Tunis. Money is also asked to improve telegraphic communication with Corsica. At present there are only three Franco-Algerian cables belonging to the Government, two of which are in a very bad condition.

Rain as a Lightning Protector.—In a Paper recently read before the Royal Meteorological Society, Captain J. P. Maclear, R.N., stated that he examined a number of trees near Cranleigh which had been struck by lightning during the thunderstorms of June 6, 7, 1889, and found that those which were struck before the rain fell were shattered, while those which were struck after the rain commenced were simply scored, with the bark blown off.

Express Messengers for London.—A conversazione will take place on Saturday, 12th of July, at the Royal Institute of Painters in Water Colours, at which the Duke of Abercorn will give a short description of the "Messenger Call System" and its advantages. Captain Davies, of the Exchange Telegraph Company, who was the first to introduce the "call system" into England, has kindly arranged to fix up an installation exhibiting the system in actual operation.

Aberdeen.—The Gas Committee of the Town Council met on Monday to consider the Provisional Order as altered by the Board of Trade. The charge for providing electricity for lighting purposes is fixed at 13s. 4d. per quarter for 20 units, every additional unit being charged at the rate of 8d. The Committee resolved to make a representation that Aberdeen, in consideration of its distance from the coal fields, and the wide area to be supplied, should be empowered to exact a charge of 9d. a unit.

Telephonic Extensions in Hampshire.—On Monday the new trunk line between Southampton, Bournemouth, Poole and Christchurch was formally opened for traffic. This line practically completes the work the Western Counties Telephone Company intend to carry out in South Hants for the present. The following is the number of subscribers in each of the towns now in telephonic communication:—Portsmouth, 220; Southampton, 125; Winchester, 10; Bournemouth, 250; Boscombe, 20; Poole, 18; and Christchurch, 12.

The Double-Carbon Lamp Litigation.—The Circuit Court of the United States for the northern district of Illinois has granted an injunction restraining the Sperry Electric Company, until the final hearing of the action, "Gresham *v.* Blodgett," from making, selling, offering for sale, or using any double-carbon lamps in which two or more pairs of carbons are independently adjusted and regulated, and are burned successively, as set forth and claimed in the first claim of letters patent No. 219,208, granted to Charles F. Brush, September 2, 1879.

The Copper used by Electrical Companies.—The following are a few figures with regard to the amount of copper used by some electrical companies in the United States. The Boston Edison Lighting Company has about 530 tons of copper wire buried under the streets. The New England Telephone and Telegraph Company have in underground service nearly 260 tons of copper. The American Telephone and Telegraph Company use about 900 tons. The Thomson-Houston Electric Company have built electric railways taking over 700 tons of copper.

Electric v. Steam Locomotion.—In a Paper by Mr. O. T. Crosby, read at the Boston meeting of the American Institute of Electrical Engineers, he comes to the conclusion (1) that a low-speed armature placed on the car axle would place the electric motor in the lead at all service speeds; (2) for speeds above 70 miles per hour a geared electric motor with 20 per cent. loss would prove more economical than the steam locomotive save in cases of very infrequent service on long lines; (3) at speeds of 100 miles per hour and upward neither steam at 90 per cent. nor electric apparatus at 60 per cent. is commercially practicable.

Southend.—At a special meeting of the Southend Local Board, the contract with Messrs. Crompton and Co. for doing the temporary and permanent work in connection with the electric lighting and tramway on the new pier was agreed to. The contract provides that the temporary work is to be finished by August 1st, under a penalty of £10 a day. The permanent works are to be finished by May 1, 1891. Messrs. Crompton are to run and work the tramway this season and one month next season; and they undertake to pay £5 a day for every day upon which the tramway ceases to work for two hours.

Thunderstorms.—On Friday last a violent thunderstorm visited Sunderland. The telephone apparatus at the Central Police Station and two houses were struck. During a thunderstorm at Skendleby, near Spilsby, on Saturday, a man in charge of a mowing machine was struck by lightning and killed, together with the horse attached to the machine. At Teignmouth two boys were struck by lightning. At Warrington a house was struck. In the neighbourhood of Wooler, on Thursday, a flock of 33 sheep, which had sought shelter in an uninhabited house, were all killed by a flash of lightning which struck the house.

The Edinburgh Meeting of the Institution of Electrical Engineers.—We are informed that both the London and North-Western and the Midland Railway Companies have consented to issue to any members of the Institution who may be proceeding to the Edinburgh meeting, return tickets of any class, available for eight days, at the same reduced price as has been agreed to by the Great Northern Company, viz., a single fare and a quarter. The tickets will be issued from any of the stations of these companies' lines on production of a note signed by the Secretary. A circular respecting these notes, accompanied by a programme of the proceedings, will be issued in a few days to all who may have intimated their intention to attend the meeting. Over 100 names have already been sent in.

The Lighting of the City.—At the last meeting of the Commissioners of Sewers the Solicitor stated that he had received what purported to be an agreement from the solicitor of the Laing, Wharton, and Down Syndicate on the part of the alien Company at Boston—the Thomson-Houston Company—as to the question of a guarantee. As there was no time now to get the formal agreement exchanged between the alien Company at Boston, he thought it would be unwise to throw up the Provisional Order on the technical ground that the guarantee had not been sent. A lengthy discussion ensued, and an amendment was moved that no consent should be given to a Provisional Order without the guarantee. Voting then took place upon the amendment, with the result that it was lost by three votes.

The Paris Central Stations.—The *Bulletin International de l'Electricité* estimates that three-quarters of the total available engine-power at the Paris central stations lies idle for twelve hours out of the twenty-four. It suggests as a means of

Digitized by Google

employing these engines that industries requiring power should be established adjoining the central stations, and the spare power utilised in this way during the hours of light load.—The Conseil d'Hygiène et de Salubrité de la Seine has decided to place electric lighting stations employing more than 100 indicated horse-power in the class of "dangerous establishments." In the report of M. Michel Lévy upon this subject, it is stated that the horse-power of the 20 central stations of Paris now amounts to 10,000, or one-sixth of the total motive power used in the Department of the Seine.

The Rotation of the Plane of Polarisation as a Measure of Current.—In 1851 Wiedemann discovered that if a tube containing bisulphide of carbon is surrounded with a wire carrying a current, the rotation of the plane of polarisation is exactly proportional to the strength of the current. Starting from this point M. d'Arsonval has devised a very simple arrangement for measuring currents and testing the accuracy of ammeters. In the apparatus recently shown to the Société de Physique, a coil of wire was wrapped round an ordinary saccharimeter tube containing pure water or bisulphide of carbon. The E.M.F. of a single Leclanché cell will cause a rotation of 1deg. The apparatus can be made as sensitive as one pleases, since for a given current the sensilibity depends simply upon the number of convolutions of the coil.

The Mechanical Equivalent of Light.—According to Dr. O Tumlirz a surface of one square centimetre placed vertically at a distance of 1 metre from an amyl-acetate lamp, so that it is normal to the rays, receives in each second a quantity of light, the energy of which is equivalent to a heat energy of

$$361 \times 10^{-9} \text{ calories,}$$

or to an electrical energy of

$$(1{\cdot}226 \text{ milliamperes})^2 \times 1\Omega.$$

Taking this in conjunction with the statement of S. P. Langley that 1 square cm. of the earth's surface, under vertical incidence of the sun's rays, receives in a minute 2·84 calories, it will be seen that the sun's light can be replaced by 1,020 quadrillion units of light, or 820 quadrillion normal German candles.

Accumulators with Porous Partitions.—In connection with M. Regnier's latest form of storage cell, referred to by our Paris correspondent in our issue of June 20th, M. Chatiliez, manager of the Verdun water power electrical station, writes to *L'Electricien* to say that he has met with considerable success by employing ordinary porous partitions between the battery plates. These partitions are fluted to admit of the introduction of the electrolyte and pierced with holes to allow the liquid to circulate, and to diminish the internal resistance. The end plates rest against india-rubber washers. M. Chatiliez states that a series of experiments with these plates have shown that the grids may be made lighter and the perforations larger than usual without detriment. The internal resistance of the cells may be kept within moderate limits by slightly increasing the density of the solution.

The Government and the Telephones.—The Duke of Marlborough intends to ask the House of Lords to agree to a resolution declaring it advisable that telephone licences shall be granted to responsible parties willing to undertake the business of forming new telephone companies on the expiry of the patents owned by the National Telephone Company.—At its last meeting the Edinburgh Chamber of Commerce considered the announcement of the Postmaster-General with regard to the taking over of the telephone system by the Government. A strong feeling was expressed that in the public interest the telephone system should be acquired; and it was agreed to make a representation to Mr. Raikes, and to the members for the City, with a view to the Government either altering its decision or making such a statement on the question as would satisfy the public that the course proposed by the Government was a desirable one.

Notes on Thunderstorms.—Mr. R. H. Scott has contributed a note on thunderstorms to "Longman's Magazine" for June, showing various peculiarities in their behaviour in this country and abroad. These storms are generally divided into two groups: (1) heat thunderstorms (the summer type), and (2) cyclonic thunderstorms, which occur principally in autumn and winter. The frequency of the storms is much greater in low latitudes than in high, and their energy is materially moderated by the dampness of the climate; hence our own comparative immunity from them. Certain districts also appear more liable to storms than others; the damage by hail, which frequently accompanies electrical discharges, appears to be greater in Huntingdonshire and neighbouring counties than in other parts of England. From an extensive inquiry by the Berlin Statistical Office, published in 1866, it appears that houses with thatched roofs are struck by lightning much more frequently than slated houses, while houses in towns are less frequently affected than those in the country.

Italian Telegraph Statistics.—The Italian telegraph system was increased during 1889 by 1,474 kilometres of lines, and 9,704 kilometres of conductors, the total at the close of the year being 35,322 kilometres of lines and 128,209 kilometres of conductors. Of the lines 15,225 kilometres are along railways, and 20,097 kilometres along ordinary roads; of the conductors 91,671 kilometres are along railways, and 36,538 kilometres along roads. During 1888-1889, 5,322 interruptions occurred, 2,501 of these being on railway lines and 2,821 on roads; 81 cases were due to damage to the posts, 538 to broken insulators, 724 to breaking of wires; contacts and short circuits were responsible for 3,571, and lightning for 408. During 1888 and the first half of 1889 10 new cables were laid. The total length of Italian cables at the end of 1889 was 3,988 kilometres, of which only 11 cables (146·140 kilometres) belonged to the State; the remainder belonging to the Eastern Telegraph Company, Pirelli and Co., and other private companies.

An Improved Connection for Carbon Battery Plates.—A useful little improvement in the way of connecting the carbon plates of batteries has been devised by Mr. Dopping-Hepenstal, R.E. A small hole is drilled through the carbon plate about ¼in. from the upper edge. A piece of platinum wire, 24 or 22 S.W.G., is next snipped off obliquely, so as to form a chamfered end, and the last quarter of an inch or so of the piece is bent back upon itself, and pinched tight. The piece is then passed through the hole in the carbon plate, and pressed in hand tight, until arrested by the swell of the loop. A length of two to three inches will usually be found convenient. The plate may be partially or totally submerged in the exciting fluid. It does not matter whether the actual junction between carbon and platinum is above the level of the exciting liquid in the cell or below it, the platinum being, for all practical purposes, incorrodible. Thus a Leclanché cell can be sealed up, the carbon plate being entirely within the cell, and connected to the outside by a single platinum wire passing through the seal.

The Press Rates to South America.—Press messages are now transmitted from London by the cables of the Brazilian Submarine and Western and Brazilian Companies at the following reduced rates:—

	Per word. s.	d.
To Madeira	0	8
,, St. Vincent	1	6
,, Pernambuco	3	1
,, Para, ,, Maranham, ,, Ceara, ,, Bahia, ,, Rio de Janeiro	3	6
,, Santos, ,, Santa Catarina, ,, Rio Grande do Sol	3	11
,, Monte Video	4	1
,, Buenos Ayres	3	7

These telegrams are subject to the usual conditions governing press messages.

Cardiff.—Mr. E. Garcke, writing to the *Cardiff News*, says that his Company has for twelve months been unable to obtain an interview with the Corporation or their Lighting Committee. They seek no monopoly. Their intention was to undertake the lighting of the whole area within the jurisdiction of the Corporation. Mr. Garcke points out that the ratepayers can obtain the best light at the cheapest price by fair

Digitized by Google

competition between gas and electric light companies. It is true that the Brush Electrical Engineering Company can continue business as hitherto, but they cannot extend their operations by underground mains, except by the consent of the local authorities to their application for a Provisional Order. A memorial signed by 45 ratepayers supports a conference. It appears to us that the Brush Company have been very hardly dealt with in this matter. The Corporation, who desire to take every advantage of the new regulations, appear to be rather uncertain of their position, in persisting in declining even an interview with a representative of the contractors who, for the last seven or eight years, have been supplying Cardiff with electric light.

The Transfer of Provisional Orders.—In the House of Commons last week Mr. Beaufoy asked the President of the Board of Trade whether, as it was contrary to practice to allow Local Authorities by one and the same Act or Provisional Order to establish gas undertakings with power to transfer them, he would state the reasons which had led him to depart from this practice in the case of electric lighting orders which the Board had recently granted to Local Authorities. Sir M. Hicks-Beach said he had nothing to add to the replies he had already given with reference to this matter. He had confidence in the discretion of the Local Authorities, and, with the safeguards contained in the clause referred to, he did not think the interests of the public could suffer. In reply to a further question from Mr. Beaufoy, Sir M. Hicks-Beach said Section 5 of the Electric Lighting Act, 1882, required that rules made by the Board of Trade under that Act should be laid before Parliament, but there was no similar provision in respect to the model form of Provisional Order. The orders, as granted by the Board of Trade, were submitted to Parliament for confirmation, and had no force until so confirmed.

Telegraphists and Overtime.—In the House of Commons, on Tuesday evening, Mr. Lafone asked the Postmaster-General whether there was any truth in the rumour that the telegraphists had refused to work overtime? Mr. Raikes stated in reply that at the Central Telegraph Office it was impossible to carry on the work without overtime. Every effort was made, however, to restrict the overtime, and additions were made to the staff from time to time as the number of messages increased or additional wires were brought into operation. Less than a year ago authority was given to increase the number of telegraphists by 100, and no time was lost in training the new hands. The question of a further increase of the force was now under examination. The necessity for overtime was, he was sure, appreciated by the general body of the telegraphists, and he did not entertain any apprehension that these officers had it in contemplation to refuse to perform duties which were required in the interests of the public. If overtime were entirely abolished there would be a grievance on the part of a large proportion of the staff by whom the payment for the overtime was welcomed as an additional source of income.

The Dynamo Plant at the Chicago Telegraph Office.—After an experience of two years at the New York office with current supplied from dynamos instead of batteries, the Postal Telegraph Company, says the *Western Electrician*, recently decided to adopt this system in Pittsburg and Chicago. On May 1 a plant of generators was started in the latter city in the basement of the Phœnix building. The dynamos took the place of 9,000 cells. The installation consists of sixteen shunt-wound generators, and two 10-horse power 220 volt motors. The motors are fed from two separate and distinct leads from the Edison system. Although there are sixteen generators in all, one set of eight machines is all that is required for the regular service. The other set of eight machines is kept as a reserve. One dynamo in each set furnishes current to all the locals, loops, city wires, and call-box circuits. The seven others of a set range from 70 to 350 volts for main line circuits. All the leads from the dynamos connect with the instruments and line, through resistance coils. These coils are proportioned for the service required on the lines, and are introduced as a precaution against damage from the sudden short-circuiting or grounding of a line. These resistances are figured at about two ohms to one volt.

Electrolysis of the Muscles.—In a recent number of the *Bulletin de la Société Belge d'Electriciens*, Dr. G. Weiss contributes a brief account of some interesting electro-medical investigations undertaken by him. That electrolytic effects take place at the electrodes where an electric current enters and leaves the human body is, says Dr. Weiss, universally admitted; but is the electrolytic action confined to these points? Dr. Weiss then points out how, when intermittent currents of the same size are sent along the gastronemian muscles of a frog's leg, the contractions rapidly cease, and no amount of rest restores the muscles to their primitive condition. On the other hand, the duration of an alternating current does not perceptibly affect the contractions. This phenomenon points, therefore, to electrolysis of the muscle along the entire path of the current. Dr. Weiss then tested this theory as follows. He took two vessels containing a 1 per cent. solution of chloride of sodium, connected them by a syphon filled with the same liquid, and passed a given current from vessel to vessel, using platinum electrodes. The experiment was then repeated with the two hind legs of a frog as connecting piece. The E.M.F. of polarisation was considerably greater in the latter case than in the former. Dr. Weiss is of opinion that an electric current traversing a muscle gives rise along the whole length of its path to chemical decompositions, and that the products of these give rise in their turn to powerful secondary actions upon the substance of the muscles, which are rapidly attacked and destroyed. Microscopic examinations showed that the entire structure of a muscle was gradually altered by the passage of a current. Dr. Weiss then poured a strongly saline solution of gelatine, coloured with well neutralised-turnsol, into a U tube, and when the gelatine had solidified he poured in water coloured in a similar manner. The turnsol not only changed colour at the platinum electrodes but also at surface, separating the gelatine and the water. With albuminous water the albumen was coagulated at the positive and completely dissolved at the negative surface of separation.

Accumulators at the Berlin Telegraph Office.—In a Paper recently read before the Elektrotechnischer Verein, Herr Strecker, chief engineer to the German Imperial Telegraph Department, gave a brief account of the accumulators, which had been installed in Berlin in connection with the telegraph service. In October last a battery of 25 Tudor accumulators, having a capacity of 25 ampere hours, was installed at the Berlin telegraph offices. The cells are charged with a current of 7 amperes by a shunt-wound Siemens machine, driven by a 5 horse-power Otto engine. The current is conveyed to the central office, distant 1·7 kilometre, by means of a seven-wire cable, each wire having 5 ohms resistance. Only three wires are at present used, and they convey the current in the following manner: The first, starting from the eighteenth cell of the battery, supplies 36 circuits at 34 volts; the second, starting from the twentieth cell, supplies 12 circuits at 40 volts; the third starts from the last cell of the battery, and supplies 13 circuits at 50 volts, six circuits at 60 volts, and one circuit at 80 volts. In the two last circuits 10 and 30 primary cells respectively are added to the secondary cells. These 68 lines comprise 41 Morse and 27 Hughes circuits. The negative pole of the battery is connected to earth. The average discharge is at the rate of 60 milliamperes, so that the accumulators can supply this from 30 to 40 days, although, as a matter of fact, they are charged every ten days. The charging is effected in the following manner:—The dynamo is switched on to the accumulators through a very high resistance, so that the charging current is at first very small indeed. A wire is taken from the centre of the battery to earth through a voltmeter, and when the E.M.F. rises by about 2 volts, the engineer in charge, by means of a switch, switches out a cell from the telegraph circuits, still leaving it in the charging circuits. The charging current is then increased, and as the E.M.F. rises still further more cells are switched out. The reverse process is gone through on stopping. The difference of potential on the telegraphic circuit during the charging operations is kept so uniform that no complaints have ever been received from the central office. Since the cells were first employed in the beginning of October, 1889, they have worked in an irreproachable manner, and the authorities are so satisfied with them that they now propose to adopt them on a far larger scale

MAGNETISM IN IRON AND OTHER METALS.*—XXII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 197.*)

§ 87. **Lord Rayleigh's Experiments.**—The inference drawn by Baur as to the value of κ when H is zero depends on the legitimacy of extending the straight line connecting κ and H backward beyond the region of actual experiment to cut the axis of κ. It has been entirely confirmed by the experiments of Lord Rayleigh,† who has examined the action of much feebler magnetic forces, and has found that the proportionality of magnetic induction to magnetic force continues to hold good when the force is excessively reduced.

In his experiments a bar or wire of iron was tested magnetometrically with one end very near the magnetometer, and with a compensating coil adjusted to balance the magnetism which a feeble magnetising current induced in the bar. The specimen under examination being a piece of Swedish iron wire (not annealed), the compensating coil was adjusted so that there was no movement of the magnetometer needle when a magnetising current was made or broken, the strength being such as to give a field of 0·04 C.-G.-S. Then the strength of the current was gradually reduced till the magnetic force fell to about 0·00004, and it was found that the compensation remained perfect. In other words, within these limits the induced magnetism was proportional to the inducing force: κ and μ were constant. "In view of this," says Lord Rayleigh, "neither theory nor observation give us any reason for thinking that the proportionality would fail for still smaller forces." Quite similar results were obtained with other specimens of unannealed iron and of steel. The range through which κ and μ are sensibly constant is much less in annealed than in hard iron. Within this range of force there is no retentiveness; the magnetising process begins like the straining of a solid body with an elastic stage within which there is no "permanent set." When the magnetising force was increased above 0·04 the compensation failed to remain exact, and the deviations followed the parabolic law stated above. The formulas

$$\kappa = 6{\cdot}4 + 5{\cdot}1\,\mathsf{H}$$
$$\mu = 81 + 64\,\mathsf{H}$$

agreed well with the results of experiment for values of H ranging up to 1·2 C.-G.-S. unit. (In comparing these with the formula given in the last paragraph, it must be remembered that they refer to hard iron, the others to annealed iron: the initial susceptibility is less here, and the deviation from the initial value is very much less rapid.) With another specimen of hard-drawn iron wire the initial value of μ was 87.

Lord Rayleigh has also examined the effect of alternately applying and removing a small amount of magnetic force, when the piece is kept more or less strongly magnetised by means of a constant force. So long as the constant force is moderately small, and the mean magnetisation consequently not very strong, the susceptibility with regard to alternate applications and removals of a small part of the force is not materially different from the initial susceptibility of the same piece when unmagnetised. But as the mean magnetisation is raised, the susceptibility with respect to small changes of force becomes reduced. In a piece of hard iron a steady force of 29 C.-G.-S. had the effect of reducing the susceptibility with respect to small alternations by about 40 per cent. of its original value; and in a piece of annealed iron the reduction due to the same steady force was more than 80 per cent.

§ 88. **Magnetic Viscosity under Small Forces.**—Allusion has already been made (§ 50) to the fact that after any change has taken place in the magnetic force acting on a piece of soft annealed wrought iron, some time elapses before the corresponding change of magnetic state is complete.‡ This magnetic viscosity is most noticeable when we have to deal with feeble forces or with small changes of force, and when the specimens tested are of considerable size. In such cases the time-lag in magnetisation may be so great that the ballistic method, which, of course, omits to take note of slow continuous changes, is not properly applicable.

In describing the experiments which were referred to in the last paragraph, Lord Rayleigh remarked that in applying small magnetic forces to *hard* iron or steel it was possible to adjust the compensating coil, so that neither at the moment of closing the magnetising circuit nor afterward was there any deflection—which means that, so far as the magnetometer can decide, these metals take their full magnetism at once. With annealed wrought iron, however, the effects were more complicated. "When the coil

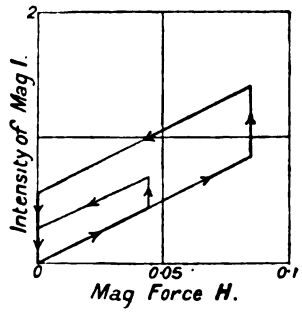

FIG. 57.

was so placed as to reduce as much as possible the instantaneous effect, there ensued a drift of the magnetometer needle in such a direction as to indicate a continued increase of magnetisation. Precisely opposite effects followed the withdrawal of the magnetising force. The settling down of the iron into a new magnetic state is thus shown to be far from instantaneous."

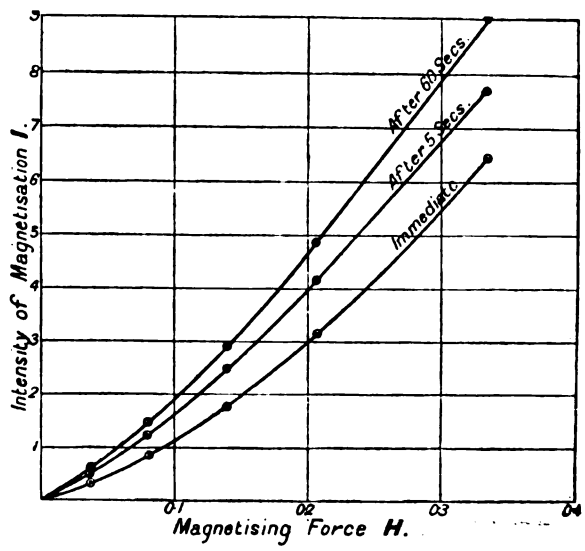

FIG. 58.—Effects of applying feeble magnetising forces to a soft iron rod.

Following Lord Rayleigh's plan of balancing the instantaneous effect by means of a compensating coil, and then observing the drift, the writer examined this time-lag in the magnetisation of a thick wire of annealed wrought-iron 0·404 cm. in diameter and 39·6 cms. long.* The wire was demagnetised by reversals to begin with, and feeble magnetising forces were used, not at first exceeding 0·1 C.-G.-S. So long as the force was less than this it was found that one adjustment of the compensating coil served to balance the instantaneous effect of making or breaking the current. When the compensation was correct the magnetometer needle began to drift slowly over as soon as the magnetising force was either applied or removed; and by observing the drift and adding that to the amount neutralised

* All rights are reserved.

† *Phil. Mag.*, March, 1887.

‡ Phil. Trans., 1885, p. 569.—"When the magnetising current was applied to long wires of soft iron, either gradually or with more or less suddenness, there was a distinct creeping up of the magnetometer deflection after the current had attained a steady value. This action was sometimes so considerable as to oblige me to wait for some minutes before taking the magnetometer reading."

* *Proc.* Roy. Soc., June 20, 1889.

Digitized by Google

by the compensating coil, the total magnetism after any time was readily deduced. A force of 0·044 C.-G.-S. was applied, and the instantaneous effect was to produce a value of I equal to 0·44 ; in five seconds this crept up to 0·58, and in 60 seconds to 0·67. Then the magnetising current was broken ; the instantaneous effect on I was to remove 0·44, leaving 0·27 ; in five seconds this residue fell to 0·09, and before 60 seconds it had completely disappeared. Next a magnetising force of 0·084 was applied. The value of I reached at once was 0·85 ; in five seconds it crept up to 1·20, and in 60 seconds to 1·40. On breaking the current, I fell at once to 0·55, after five seconds to 0·23, and after 60 seconds to 0·07. Possibly this small residue was permanent. These results are shown in Fig. 57. Precisely similar results were obtained by reversing feeble magnetic forces, the initial gradient of the lines being the same when the force was reversed as when it was applied and removed. If we measure the initial susceptibility by the immediate effect of applying or reversing H it is 10 ; if we measure it by the effect after one minute it is about 15.

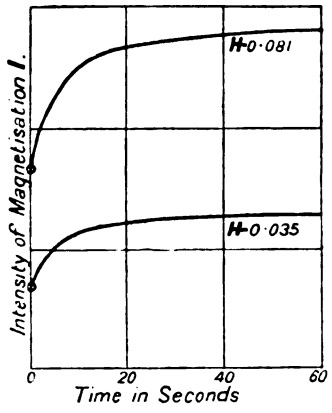

Fig. 59.—Growth of magnetism after applying feeble magnetising forces.

Fig. 58 shows the results of another experiment, in which successive forces were applied, ranging up to about 0·34 C.-G.-S., the compensating coil being adjusted for each force to give an instantaneous balance, so that the effect of the subsequent creeping up might be observed. Before applying each force the specimen was completely demagnetised. The three curves, Fig. 58, show the amounts of magnetism taken (*a*) at once, (*b*) after five seconds, and (*c*) after one minute. In noting the gradual growth of magnetism after each force was applied, readings of the magnetometer were taken every five seconds, and the two curves of Fig. 59 have been drawn from these, to show the time rate at which the process of creeping up went on under the action of magnetising forces equal to 0·035 and 0·081 respectively.

(To be continued.)

The Passive State of Iron and Steel.—In a Paper on this subject recently read before the Royal Society, Mr. Thomas Andrews gives the results of his latest investigations in this direction. The results afford an indication that magnetisation of comparatively low intensity, acting during considerable periods of time, exerts only a limited modifying influence on the passivity of iron or steel in the cold, though the influence is discernible when employing a delicate galvanometer. Magnetisation, with the nitric acid at a higher temperature, produces a quicker effect. In a recent research by the author, on "Electro-Chemical Effects on Magnetising Iron," it was noticed that local currents were set up between the polar terminals and central portions of steel magnets exposed as electrodes ; and this class of local action, together with the slight alteration of the physical structure of the magnet bars consequent on their magnetisation, may possibly be involved in producing the effects due to magnetism on passive steel or iron in concentrated nitric acid.

THE CAPE TOWN CABLE STATION.

BY H. D. WILKINSON.

With the extension of the system of submarine cables and the ultimate duplication of existing lines it becomes a matter of necessity to have means for storing cable at convenient points on shore, where it may be kept in good condition, and drawn from as required by the repairing steamers. For this purpose tanks have been erected on shore at Gibraltar, Malta, and Suez, in which cable is stored for the maintenance of the network of cables in the Mediterranean, while there are also tanks at Perim, and storage hulks moored off Zanzibar and Mossamedes for the same purpose. And now that, with the exception of the Government land lines between Cape Town and Natal, the dark continent is completely encircled by submarine cables, it has been decided upon by the Eastern and South African Cable Company, whose lines extend between Aden and Delagoa Bay on the East, and between Cape Town and Loanda on the West Coast, to erect tanks with ample storage capacity at the terminal station of Cape Town. The usual practice is to construct the tanks of riveted iron plates, similar to those on board cable-ships, and to erect them inside a covered shed of light angle-iron girders. An exception to this exists at Malta, where the tanks, or rather wells, are of concrete, opening flush with the ground.

The site for the tank-house at Cape Town has been selected on the promontory of land from which the new breakwater starts, immediately overlooking the docks. From this situation cable can be conveniently led over to a cable-ship in dock by simply crossing the dock road on overhead leads. The building, which is of corrugated iron, covers a space of nearly 6,000 square feet. In Fig. 1 we have a sectional view of the building, showing the position of the tanks. Derricks are erected as shown, on which to suspend the leading-in pulleys, and at the point of entering or leaving the shed the cable passes between two vertical rollers (Figs. 1 and 3). The sectional view shows the arrangement of pulleys and hauling gear. For the latter an engine and boiler are fixed as shown. The engine is an ordinary double-cylinder winch-engine, with 7in. cylinders and 15in. stroke, fitted with reversing gear. The motion is transmitted to the hauling pulley by a vertical shaft driven from the engine and connected by speed-reducing bevel gear. Altogether the speed is reduced in the ratio of 8 : 1.

The cable passes, as shown, over the V pulley, being kept down in the groove by the jockey-wheel J (Fig. 1), mounted on a lever with weight attached ; while the speed and direction are controlled by the engine the necessary grip on the cable for hauling is controlled by the position of the weight. The rim of the jockey-wheel is turned slightly concave to take the cable; but an improvement in this is to construct the wheel in two halves, adjustable towards or from each other, so as to fit over and grip any type of cable, from type D to the heavier types.

The shed contains three tanks, the centre one being 30ft. diameter and 6ft. deep, while the two others are 40ft. diameter and 8ft. deep. These have a total capacity of over 500 miles of cable. The cable passes over anti-friction pulleys fixed to the highest point in the span of the roof, and a platform is constructed at a convenient distance below them on which two or three men can work at keeping the cable taut. An improvement suggested by Mr. George Beckwith, the Company's engineer, under whose charge the erection of the plant has been carried out, is to place a second V pulley and jockey-wheel at the distant end of the shed to assist in the hauling and taking-up of the slack when cable is being led in to the further tank, the same being connected to the driving power by an overhead horizontal line of shafting. This arrangement would dispense with the hand labour of three men

Each tank is provided with an inlet and outlet service, by which water can be admitted or drained off, the inlet pipes being connected to the Harbour Board pumping engine in the docks supplying the convict station. The tanks are bedded on to a foundation consisting of rough concrete, 1ft. 6in. deep, covered with a 1½in. layer of cement and sand. Before this layer has set, the tank is let down and grouted in all round. A layer of cement is also run into the interior of the tanks,

Digitized by Google

this being 1½in. deep round the circumference and sloped down to 1in. at the centre to assist in draining off. The leading pulleys over which the cable passes to the tanks are mounted on rollers R R, as shown (Fig. 2), reducing the friction to a minimum. A suitable testing-room is also fitted up in the tank-house, and provided permanently with instruments.

The last section in the chain of cables on the East Coast was laid as recently as last year. This connects the port of Mossamedes with Cape Town, the cable being 1,383 knots in length.

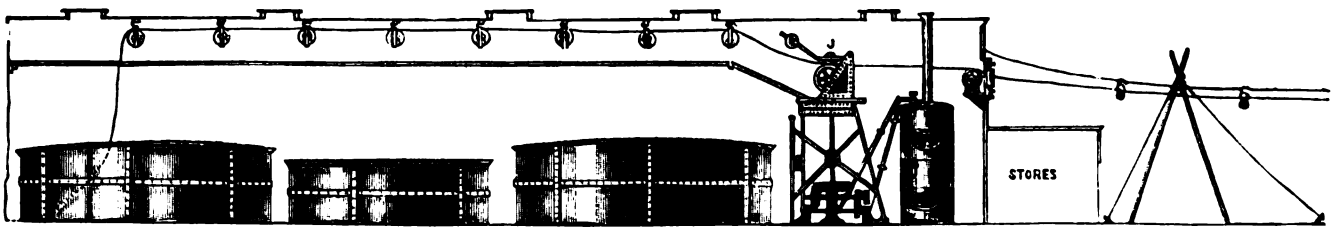

Fig. 1.—Cable tanks and hauling gear.

At a point some 384 miles from Cape Town a short length of cable is connected on to this cable by a T joint, and taken into the intermediate station of Port Nolloth. This joint, instead of being completely armoured over as in an ordinary joint, is enclosed and sunk in a cast-iron box. The strain is then taken off the joint by turning back the wires of the armour through holes in the box, and making them

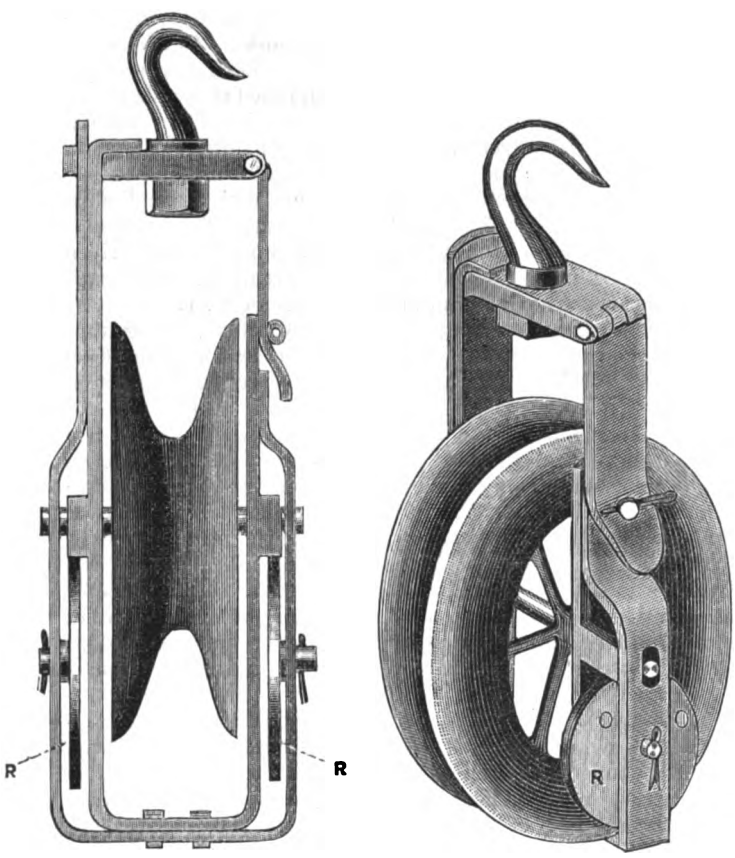

Fig. 2.—Anti-friction cable lead.

fast to the main cables. At Cape Town the cable has been laid round the outer bend of Table Bay, well outside the limits of the anchorage, and its course indicated by a series of mark buoys. The Cable House stands close to the old jetty at the bottom of the main street (Adderley-street), and is connected to the office in the same street by about a quarter of a mile of type D laid underground. The office itself is situated in the Standard Bank Buildings, the finest and most prominent building in this thoroughfare, and consists of an instrument room, battery and testing room, store room, and receiving office on the ground floor, and superintendent's office on the first floor. One remarks on entering that there is ample room for everything, not often the case in cable stations, and that the rooms are particularly lofty. One syphon recorder is, of course, only necessary, as messages for stations in the Colony and for the West Coast pass over the Government land lines, and are handed over to their offices. A mirror instrument is, however, kept in reserve. The recorder is of the latest pattern (see *Electrician*, June 20, 1890, p. 170), permanent magnets being employed. By reference to the signals on this cable herewith reproduced (Fig. 4), it will be seen that they are for this length of cable, and the vibrator method of driving the ink very clearly defined. The line has a capacity of 549 microfarads, a resistance of 8,832 ohms, an insulation of 8,500

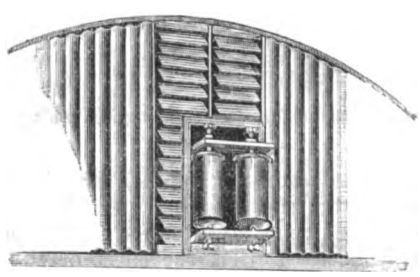

Fig. 3.—In-leads to tank house.

megohms per knot, and 20 microfarads are signalled through at each end.

This account of the station, though so brief, could not well be considered complete without some mention being made of the staff quarters. These are well situated on rising ground in Caledon street, and from the upper balcony command a fine view of Table Bay. The house, known as Buckingham Lodge, is surrounded by a tastefully laid-out garden, and approached through a thick avenue of trees. There are some twelve rooms, besides mess room and billiard room; a certain portion being reserved for the superintendent's use. As this station, from its

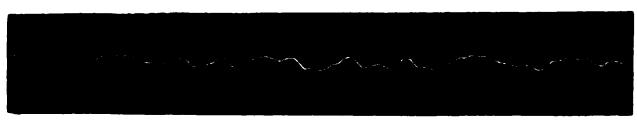

Fig. 4.—Signals on Cape Town Mossamedes cable. 1383 knots.

temperate and agreeable climate, is also used as a sanitorium for men who may be invalided from stations on the coast, the Company have spared no pains to make the quarters well appointed in every way. To the superintendent, Mr. Thomas Cassidy, is due most of the general arrangements for the comfort of the staff; and it is to his courtesy, and that of the staff working with him, that we are indebted for much of the information obtained.

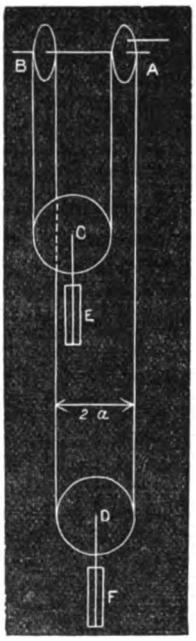
ON HUYGENS'S GEARING IN ILLUSTRATION OF THE INDUCTION OF ELECTRIC CURRENTS.*

BY LORD RAYLEIGH, SEC. R.S.

As a mechanical model of the electric machinery at work in the induction of currents Maxwell employed differential gearing; and an apparatus on this principle, designed by him, is in use at the Cavendish Laboratory. Wishing to show something similar in a recent course of lectures, and not having differential gearing at my disposal, I designed more than one combination of pulleys, the action of which should be analogous to that of electric currents. These eventually resolved themselves into Huygens's gearing, invented, I believe, in connection with the winding of clocks. As this apparatus is easier to understand than differential gearing, and the parts of which it is composed are more likely to be useful for general purposes in a laboratory, I have thought that it might be worth while to give a description, accompanied by an explanation of the mode of action.

Two similar pulleys, A, B, turn upon a piece of round steel fixed horizontally.† Over these is hung an endless cord, and the two bights carry similar pendent pulleys, C, D, from which again hang weights, E, F. The weight of the cord being negligible, the system is devoid of potential energy; that is, it will balance, whatever may be the vertical distance between C and D. Since either pulley A, B, may turn independently of the other, the system is capable of two independent motions. If A, B turn in the same direction and with the same velocity, one of the pendent pulleys, C, D, rises, and the other falls. If, on the other hand, the motions of A, B, are equal and opposite, the axes of the pendent pulleys and the attached weights remain at rest.



In the electrical analogy the rotatory velocity of A corresponds to a current in a primary circuit, that of B to a current in a secondary. If when all is at rest the rotation of A be suddenly started, by force applied at the handle or otherwise, the inertia of the masses E, F, opposes their sudden movement, and the consequence is that the pulley B turns *backwards*, *i. e.*, in the opposite direction to the rotation imposed upon A. This is the current induced in a secondary circuit when an electromotive force begins to act in the primary. In like manner, if A, having been for some time in uniform movement, suddenly stops, B enters into motion in the direction of the former movement of A. This is the secondary current on the break of the current in the primary circuit.

It must be borne in mind that in the absence of friction there is nothing to correspond with electrical resistance, so that the conductors must be looked upon as perfect. The frictions which actually enter do not follow the same laws as electrical resistances, and only very imperfectly represent them. However, the frictions which oppose the rotations of A and B have a general effect of the right sort; but the rotations of C and D, corresponding to dielectric machinery, should be as free as possible.

The effect of a condenser, to which the terminals of one of the circuits is joined, would be represented by a spiral spring (as in a watch) attached to the corresponding pulley, the stiffness of the spring being inversely as the capacity of the condenser. The absence of the spring, or (which comes to the same thing) the indefinite decrease of its stiffness, corresponds to infinite electrical capacity, or to a simply closed circuit.

The equations which express the mechanical properties of the system are readily found, and are precisely the same as those applicable in the electrical problem. Since the potential energy vanishes, everything turns upon the expression for the kinetic energy. If x and y denote the circumferential velocities in the same direction of the pulleys A, B, where the cord is in contact with them, $\frac{1}{2}(x+y)$ is the vertical velocity of the pendent pulleys. Also $\frac{1}{2}(x-y)$ is the circumferential linear velocity of C, D, due to rotation, at the place where the cord engages. If the diameter be here $2a$, the angular velocity is $(x-y)/2a$. Thus, if M be the total mass of each pendent pulley and attachment, Mk^2 the moment of inertia of the revolving parts, the whole kinetic energy corresponding to each is

$$\tfrac{1}{4}M\left\{\frac{(x+y)^2}{4}+\frac{k^2}{a^2}\frac{(x-y)^2}{4}\right\}.$$

For the energy of the whole system we should have the double of this, and, if it were necessary to include them, terms proportional to x^2 and y^2 to represent the energy of the fixed pulleys. The reaction between the pulleys, A, B, depends upon the presence of a term xy in the expression of the energy. We see that this would disappear if $k^2=a^2$; as would happen if the whole mass of the pendent pulleys and attachments were concentrated in the circles where the cord runs. The case discussed above, as analogous to electric currents, occurs when $k^2<a^2$, a condition that will be satisfied, even without non-rotating attachments, if the cord run near the circumference of the rotating pulleys. The opposite state of things, in which $k^2>a^2$, would be realised by carrying out masses beyond the groove, and thus increasing the rotatory in comparison with the translatory inertia. In this case the mutual action between A and B is reversed. If when all is at rest A be suddenly started, B moves forward in the *same* direction. Otherwise C and D would have to rotate, and this in their character of fly-wheels they oppose.

Generally, if L, N be the coefficients of self-induction, and M mutual induction, we have (constant factors being omitted)

$$L=N=a^2+k^2,$$
$$M=a^2-k^2.$$

In order to imitate the case of two circuits coiled together in close proximity throughout, we must have in the mechanical model $k^2=0$; that is, the rotatory inertia of the pendent pulleys must be negligible in comparison with the translatory inertia. Also the energy of the fixed pulleys, not included in the above expressions, must be negligible. If these conditions be satisfied, a sudden rotation imposed upon A generates an *equal* and opposite motion in B.

* *Phil. Mag.*, communicated by the Physical Society.

† Light wooden laths, variously coloured and revolving with the pulleys, render the movements evident at a distance.

NOTE ON A NEW PHOTOMETER.*

BY EDWARD L. NICHOLS.

Methods of photometry, which take no cognisance of differences of quality, are so ill adapted to the study of sources of light which differ from each other widely in temperature, that the introduction of some instrument by means of which both the character and intensity of an illuminant can be readily determined, would be a desirable adjunct to the equipment of our photometer rooms. The instrument which it is my purpose to describe has been designed to meet this need. Existing types of the spectrophotometer may be made to give good results, but they are expensive instruments, and so difficult to use that it is only in the hands of observers of considerable experience that accuracy is assured.

The new apparatus, the "horizontal-slit" photometer, is, in point of fact, a spectrophotometer, in which the polarising device is entirely done away with. In it the extremely simple principle of the Bunsen photometer is applied successively to the various regions of the visible spectra of the source of light which are to be compared. A direct vision spectroscope of Browning's form is attached to the usual car of a Bunsen photometer, from which the disc and mirrors have been removed. The optical axis of the collimator is horizontal and at right angles to the photometer bar. The slit is horizontal and lies in a straight line joining the sources of light, which are set up in the usual manner at the ends of the bar. The bar itself is preferably of considerable length—in the case of the one upon which the original instrument under consideration was mounted it was 500cm. long—and should be divided into 1,000 equal parts. In front of the spectroscope slit are placed two right angled prisms of the same size, and made of the same glass (see cut). Their vertical adjacent edges bisect the slit, and light travelling from either end of the photometer bar is totally reflected by them, and enters the right and left hand end of the slit in a direction parallel to the optical axis of the collimator tube. The two sets of rays thus gathered into the spectroscope from the lights at the end of the bar are vertically dispersed by the Amici prisms, and appear in the field of view as two vertical spectra standing side by side. Equal wave lengths are in the same horizontal line, and any desired region may be brought into the centre of the field by an angular movement of the ocular telescope. The telescope moves along the arc of a suitably divided semicircle, to which it may be clamped by means of a set screw. Wave lengths, corresponding to the various circle settings, are determined once for all by observation of the more prominent of the Fraunhofer lines.

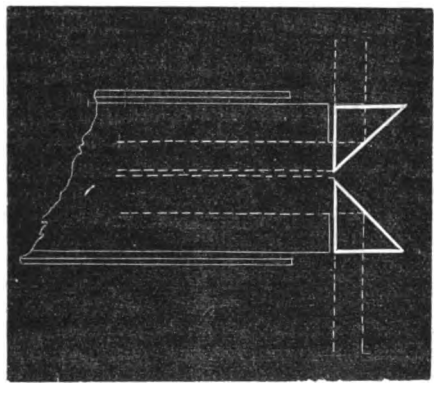
* Paper read before the American Institute of Electrical Engineers at Boston.

Digitized by Google

When the instrument thus mounted is placed at the middle of the photometer bar between lamps which are identical in intensity and quality, the two spectra are of equal brightness throughout, wave length for wave length, from red to violet. If the two lamps differ in intensity but not in quality, the two spectra will differ in brightness by the same amount from end to end, and a position may be found upon the bar for which they will be identical throughout. Under these circumstances, which are the only ones in which the Bunsen method in photometry is strictly applicable, the instrument may be used as a simple photometer, the setting for any wave length whatever giving the candle-power. For this purpose alone, viz., for the comparison of lights of similar character, the instrument offers certain manifest advantages over the various forms of the Bunsen photometer. In the course of the present Paper I shall present some definite data concerning the relative sensitiveness of the two instruments when used in this way.

When the lights to be compared differ both in intensity and quality, ordinary photometric indications possess no perfectly definite significance. In this, which is the more general case, the relative brightness of the spectra of the two sources varies with the wave length. For each region of the visible spectrum, however, a position upon the photometer bar can be found at which the brightness of the two spectra in that region will be equal; and the observations thus obtained, when extended over the entire spectrum, will afford data by means of which the differences in quality of the two sources of light may be definitely expressed.

In a recent Paper read before the Institute of Electrical Engineers, for a considerable range of temperature at least, the ratio between the intensities of a certain wave-length of the spectrum of glowing carbon, is identical with the ratio of candle-powers, as determined by the Bunsen photometer. The wave length in question, determined from the intensity of the spectrum of incandescent lamps at various candle-powers, I had found to be approxi-



mately $\lambda = 600$. M. A. Crova, in an important Paper presented at the late Electrical Congress at Paris, has pointed out the importance of this method of measuring the light from sources differing in temperature. The wave length which he has indicated for this purpose is $\lambda = 582$, which belongs to a region lying slightly farther towards the green than the one which I had adopted. When the wave length of this region has been established beyond question, the photometry of lights which vary in colour will have been reduced to a definite scientific basis. Instead of attempting to use the Bunsen photometer in measurements to which it is not adapted, we shall be able to deduce the relative candle-power of two sources of light from the comparison of a single wave length, and we shall be freed from the uncertainty arising from differences of colour and from the personal errors due to the independent use of the two eyes in observation. The determination of candle-power will then be an operation of precision, even when the sources of light to be compared vary widely in temperature. It is in the opportunity of performing such observations upon the photometer bar itself, under conditions which do away with many of the sources of error inherent in the usual methods of spectrophotometry, that the chief advantage the new photometer will be found to lie.

The following set of observations, taken with the new instrument, may serve to indicate one of the uses to which it may be put. The data are taken from an investigation now in progress in the physical laboratory of Cornell University. The object in view was to compare the spectrum of a novel type of gas burner with that of an ordinary argand burner. The two lamps were set up at the ends of a photometer bar five metres long, the bar, as already stated, being divided into 1,000 equal parts. Readings were taken at six points in the spectrum. The purposes being to express the relative brightness of the two spectra, wave length for wave length; the intensity of that due to the argand burner was taken as unity throughout, and the brightness of each region of the spectrum of the flame under investigation was obtained in terms of that of the corresponding region of the spectrum of the argand. The results are given in Table I. :—

Table I.—*Comparison of the Spectrum of a Welsbach Burner with that of an Ordinary Argand Burner by Means of the "Horizontal-slit Photometer."*

From observations by Miss Ida M. Hill. (Ten observations were made in each region.)

Colour.	Wave length.	Light ratio, $\frac{\text{Welsbach}}{\text{Argand}}$.	Probable error of a single observation.
			Per cent.
Red	702	0·709 ± ·017	2·45
Yellow	589	1·476 ± ·017	1·14
	558	1·760 ± ·025	1·34
Green	500	2·395 ± ·047	1·99
Blue	466	2·738 ± ·036	1·30
Violet	439	3·090 ± ·073	2·35
		Average	1·76

I introduce these measurements here simply as an illustration of one line of work to which the instrument under consideration is adapted. A full description of the research of which they form a part, and which covers many other questions pertaining to the very interesting class of lamps with which it deals, will doubtless be published in due time. As will be seen from the column of probable errors, the sensitiveness of the instrument is greatest in the region of the D line ($\lambda = 589$), and least in the extreme red and violet, where the light intensities are small. A set of ten determinations made by the same observer with the Bunsen photometer gave for the total light ratio of the two lamps:

$$\frac{\text{Welsbach}}{\text{Argand}} = 1{\cdot}701 \pm {\cdot}015$$

The probable error of a single observation in this series amounted to 0·89 per cent., a value somewhat smaller than that obtained with the new photometer in the yellow of the spectrum. The number of observations is too small to afford a close estimate of the relative sensitiveness of the two instruments, but the results suffice to show that the "horizontal-slit" photometer does not differ appreciably in accuracy from the Bunsen photometer when the latter is used in the comparison of flames of the same colour.

When it comes to the measurement of sources of light that differ widely in temperature the comparison is decidedly in favour of the "horizontal-slit" photometer, the sensitiveness of which is not affected by differences of colour. The error of the Bunsen photometer in candle-power measurement of the arc light, for instance, calculated from ten observations recently made upon the same photometer bar, the reference standard being an argand gas burner, was 2·65 per cent. (probable error of a single observation), a value more than twice as large as that of the "horizontal-slit" photometer. A comparison of the performance of the new photometer with that of a polarising spectrophotometer of the type which is commonly recognised as affording the highest degree of accuracy, is decidedly in favour of the former. Taking as a basis eight observations made by Mr. Franklin and myself in the study of a bat's-wing gas burner, the observations covering eight regions of the spectrum, I find the error of a single observation in the various regions to have been as follows :—

Table II.—*Probable Errors of a Single Observation with a Polarising Spectrophotometer, calculated from Sets of Ten Observations upon various Portions of the Spectrum of a Gas Flame.*

Wave length.	Probable error of a single observation.
	Per cent.
753	7·9
668	4·9
608	4·5
557	5·4
518	6·4
492	7·0
468	3·0
450	2·4
	Average..... 5·9

The measurement of a fluctuating illuminant, such as the gas flame, is a line of investigation by no means adapted to exhibit any photometric instrument at its best; but as the errors of the horizontal-slit photometer, already given, were calculated from sets of ten observations upon such flames, I have selected for comparison similar sets of ten upon sources of the same character. The averages, viz. :

Error of horizontal-slit photometer 1·76 per cent. (average for spectrum), error of polarising spectrophotometer 5·20 per cent.

Digitized by Google

(average for spectrum), doubtless afford a fair indication of the relative performance of the two instruments in this peculiarly trying line of work.

At the last annual meeting of the Institute I had the privilege of presenting a brief study of certain personal errors pertaining to the use of the Bunsen photometer. The particular class of errors to which attention was called in that Paper are undoubtedly obviated by the use of the horizontal-slit photometer; what new ones the latter instrument may introduce remains to be determined.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—THURSDAY, June 26th.

London Overhead Wires Bill.

On the order for the consideration of this Bill,

Sir R. LETHBRIDGE rose to move that it be considered that day six months. He said it had been hoped that the Committee on this Bill would safeguard the rights of private residents; but the Bill conferred upon officials of the London County Council powers of compulsorily entering upon private property at any time for the purpose of putting up wires and inspecting them. Such powers had never yet been asked for in any Bill of this kind, and he trusted the House would never grant such powers to any persons whatever. It might be alleged that some means must be found to enable telephonic communication to be established; but it must be done without such interference with private rights. How it was to be done it was for the promoters of the Bill to suggest; but some method must be found against which the same objections could not be urged.

Mr. BARTLEY said the Bill would empower a Local Authority to put a pole on a house, whether the occupier liked it or not. At first the Bill was called a Subway Bill, and these wires ought to be laid in subways instead of being carried over houses and streets. He therefore hoped this Bill would be rejected and would be followed by one providing for subways for telephone wires.

SIR J. BAILEY said that the Bill in its present shape carried out exactly the report of the Select Committee of 1885, and the interests of the householder had been very carefully considered. The Bill gave the County Council power to formulate bye-laws for the regulation of overhead wires, and the enforcement of these bye-laws was entrusted to the Corporation in the City, and to the vestries and to district boards in the rest of the metropolis. The fears expressed by metropolitan members as to the effect of the Bill were absolutely unfounded. It was said that the Bill would empower the Council's officers by day or night to enter into private houses. Now, one of the great dangers of the overhead wires was that there were in London a great number of derelict wires, and therefore it was most necessary that workmen should be appointed by the Local Authorities to deal with the wires. Clause 8 of the Bill provided that the inspector of the Council might enter a private house provided he was in uniform, and was duly authorised in writing by the Local Authority, and provided that notice had been previously given. The inspector might then enter at some reasonable time to be named by the occupier. The rights of householders being thus most stringently guarded, he hoped the Bill would be read a third time.

Mr. LAWSON said that the London County Council had had very little to do with the drafting of the Bill. The question was one of public safety and convenience. It was absolutely impossible to force the telephone wires into subways; moreover, the bye-laws of the County Council would have to be approved by the Board of Trade and enforced by the district authorities. The "subways" had been dropped because that subject no longer had a place in the Bill. There could be no better arrangement than that the overhead wires should be placed under the central authority for London, acting through the various district authorities.

Mr. DIXON-HARTLAND said that he had unfortunately given a telephone company permission to put a wire over his house. Since that time the house had never been his own. The poles, moreover, were fixed so badly that considerable damage was done to the roof of his house. The Company declined to repair the damage, and it cost him £50 to put the roof in order when he applied for the removal of the poles. The question was not one of erecting telephone wires, but of erecting electric lighting wires, with the erection of which they were threatened all over London, and which was a much more serious matter. They were in the infancy of the system, and yet they had already realised that those wires greatly increased the risk of fire, a proof of which was that the insurance offices had raised the rates for that property to which electric lighting wires were fixed. He hoped the House would reject this ill-digested scheme.

Mr. BRADLAUGH urged that if the Bill passed an entirely new departure in legislation would be made; for under whatever authority the Bill was applied it would give an arbitrary power of interference with property, whether the owner objected or not, without compensation. The objections to the Bill were serious, and he trusted it would be rejected.

Sir J. LUBBOCK said the opponents of the Bill attacked solely two of its clauses, and it would surely be unreasonable to throw out the whole Bill on account of two clauses. As regarded Clause 11, the hon. member for Northampton said that the party seeking the right to put up a pole was itself to determine whether a refusal was unreasonable. That was not so; the London County Council were not owners of overhead wires, and had no interest except that of the public. Then, as regarded Clause 8, it was objected that the officers of the London County Council ought not to have any right of entry; but if they had the duty of inspection they must have some right of entry. The Bill was recommended by two Committees of the House, and he hoped the House would support the Committee.

Mr. COURTNEY remarked that this Bill had been considered by a Committee of that House, and no one could have listened to the speech of the hon. baronet who had presided over that Committee without feeling impressed with the care that had been given to the subject. He hoped, therefore, that the House would not reject in this summary manner what had been agreed to by that Committee. Another reason why they should reject this amendment was that the strongest objection against this Bill had been brought by the hon. member for Northampton, who objected to one clause of it. But even if that clause were struck out, there was much that was valuable left in the Bill, to which no substantial objection could be taken. This Bill dealt with the natural state of facts, namely, that there was a great number of overhead wires in London which formed a source of danger and inconvenience to the inhabitants of the metropolis, and it was most desirable that some authority should look after the wires. He ventured to submit that Clause 8, which had been objected to, was a very reasonable way of dealing with the question of wires already in existence, attached to houses by the permission of the owners and occupiers. He submitted that it was essential that there should be some authority able to say whether poles should be set up. The authority appointed by this Bill was the County Connecil, which had no private interest in the matter, and would only act as the guardian of the public interests. They could give notice to a person who, in their opinion, offered unreasonable objections, and if he continued to assert his objections the matter was referred to an arbitrator appointed by the Board of Trade. Those who were so devoted to the rights of property as to want special leave for the erec tion of every pole, could, if they choose, move that that clause should be rejected; but it was an entirely different thing to oppose a Bill which was admittedly a useful measure.

The House divided, when there were—

HOUSE OF LORDS.—MONDAY, June 30th.

Central London Railway Bill.

This Bill, which has already passed the House of Commons, came on Monday before a Committee of the House of Lords, consisting of Lord Henley (Chairman), Lord Brassey, Lord Rowton, Lord Hamilton of Dalziell, and Lord Yarborough.

Mr. PEMBER, Q.C., in opening the case for the promoters of the Bill, explained the details of the scheme as set forth in *The Electrician* of April 25th. There were, he said, now 17 petitions against the Bill, as compared with 37 in the other House, where the parties appeared in only 19 cases. In only eight of the petitions the parties now appeared by counsel—viz., those of the Duke of Westminster, the Duke of Portland, Lord Portman, frontagers in Oxford-street, &c., the trustees of the Paddington Estate, Queen Anne's Bounty, the Dean and Chapter of St. Paul's, and the Ecclesiastical Commissioners. Several of the petitions set forth objections to the line on the ground of vibration and danger of subsidence, and a good many objected to the underpinning clause, which was a very usual clause. Other petitions objected to the taking of the subsoil of the street without money payment. The three engineers of the scheme, Sir John Fowler, Sir Benjamin Baker, and Mr. Greathead, had a great deal too much to lose to let their names be connected with a scheme that was at all risky, and the fact of their being the engineers ought to be a sufficient guarantee that the work would be carried out properly. The objections in this case were a distinction between fear and danger. Of fear there was a great deal, but of danger there was none. There was no allegation in any of the petitions in that House with regard to the finance such as there was in the House of Commons, where, doubtless, the Committee were satisfied on that point by the evidence of Sir Henry Selwin-Ibbetson, who was one of the promoters, together with such other gentlemen as the Hon. Anthony Evelyn Ashley, Mr. Ernest Noel, and Mr. Alexander Ravenscroft Robertson.

Evidence was then called in support of the opening statement of counsel, and the Committee adjourned.

TUESDAY, July 1st.

At the second meeting of the Committee Mr. GREATHEAD was called. Cross-examined by Mr. Jeune, Q.C., in reference to St. Paul's Cathedral, Mr. Greathead said that with regard to Sir Christopher Wren's description of the subsoil near St. Paul's, which he said was composed of loose water-laden sand and shells, he was of opinion that Sir Christopher was in error. He expressed the opinion that the subsoil was clay, but had made no borings. He would be happy to do so if he obtained permission. The borings would occupy about a week.

Sir BENJAMIN BAKER, C.E., was the next witness. He was strongly of opinion that the proposed scheme could be successfully carried out.

The Committee afterwards adjourned.

WEDNESDAY, July 2nd.

At the third meeting of the Committee Sir Benjamin Baker, Dr. John Hopkinson, and Dr. Edward Hopkinson were examined.

Sir BENJAMIN BAKER was of opinion that there would be no danger to passengers from impure air in the event of a train being accidentally detained in the tunnel for any length of time.

The Committee adjourned until Thursday morning.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*
